# SQL Workbench/J User's Manual

## Table of Contents

1. General Information .....	5
1.1. Software license .....	5
1.2. Program version .....	5
1.3. Feedback and support .....	5
1.4. Credits and thanks .....	5
1.5. Third party components .....	6
2. Change log .....	7
3. Installing and starting SQL Workbench/J .....	10
3.1. Pre-requisites .....	10
3.2. First time installation .....	10
3.3. Upgrade installation .....	10
3.4. Starting the program from the commandline .....	10
3.5. Starting the program using the shell script .....	10
3.6. Starting the program using the Windows launcher .....	11
3.7. Configuration directory .....	11
3.8. Increasing the memory available to the application .....	12
3.9. Command line parameters .....	13
4. JDBC Drivers .....	17
4.1. Configuring JDBC drivers .....	17
4.2. Connecting through ODBC .....	17
4.3. Specifying a library directory .....	18
4.4. Popular JDBC drivers .....	18
5. Connecting to the database .....	20
5.1. Connection profiles .....	20
5.2. Managing profile groups .....	20
5.3. JDBC related profile settings .....	21
5.4. Extended properties for the JDBC driver .....	21
5.5. SQL Workbench/J specific settings .....	22
5.6. Connect to Oracle with SYSDBA privilege .....	26
5.7. ODBC connections without a data source .....	26
6. Editing SQL Statements .....	27
6.1. Editing files .....	27
6.2. Command completion .....	27
6.3. JOIN completion .....	27
6.4. Customizing keyword highlighting .....	28
6.5. Reformat SQL .....	28
6.6. Create SQL value lists .....	29
6.7. Programming related editor functions .....	30
7. Using SQL Workbench/J .....	33
7.1. Displaying help .....	33
7.2. Resizing windows .....	33
7.3. Executing SQL statements .....	33
7.4. Displaying results .....	35
7.5. Creating stored procedures and triggers .....	36
7.6. Dealing with BLOB and CLOB columns .....	37
7.7. Performance tuning when executing SQL .....	39
7.8. SQL Macros .....	39
7.9. Using workspaces .....	41
7.10. Saving and loading SQL scripts .....	41

7.11. Viewing server messages .....	41
7.12. Editing data .....	42
7.13. Deleting rows from the result .....	43
7.14. Deleting rows with foreign keys .....	43
7.15. Navigating referenced rows .....	44
7.16. Sorting the result .....	44
7.17. Filtering the result .....	45
7.18. Running stored procedures .....	46
7.19. Export result data .....	46
7.20. Copy data to the clipboard .....	47
7.21. Import data into the result set .....	47
8. Variable substitution in SQL statements .....	49
8.1. Defining variables .....	49
8.2. Editing variables .....	50
8.3. Using variables in SQL statements .....	50
8.4. Prompting for values during execution .....	50
9. Using SQL Workbench/J in batch files .....	52
9.1. Specifying the connection .....	52
9.2. Specifying the script file(s) .....	52
9.3. Specifying a SQL command directly .....	52
9.4. Specifying a delimiter .....	53
9.5. Specifying an encoding for the file(s) .....	53
9.6. Specifying a logfile .....	53
9.7. Handling errors .....	53
9.8. Specify a script to be executed on successful completion .....	53
9.9. Specify a script to be executed after an error .....	54
9.10. Ignoring errors from DROP statements .....	54
9.11. Changing the connection .....	54
9.12. Controlling console output during batch execution .....	54
9.13. Running batch scripts interactively .....	55
9.14. Setting configuration properties .....	55
9.15. Examples .....	55
10. Using SQL Workbench/J in console mode .....	57
10.1. Entering statements .....	57
10.2. Exiting console mode .....	57
10.3. Setting or changing the connection .....	58
10.4. Displaying result sets .....	58
10.5. Running SQL scripts that produce a result .....	59
10.6. Controlling the number of rows displayed .....	59
10.7. Controlling the query timeout .....	60
10.8. Managing connection profiles .....	60
11. Export data using WbExport .....	62
11.1. Memory usage and WbExport .....	62
11.2. Exporting Excel files .....	62
11.3. General WbExport parameters .....	63
11.4. Parameters for text export .....	67
11.5. Parameters for XML export .....	69
11.6. Parameters for type SQLUPDATE, SQLINSERT or SQLDELETEINSERT .....	69
11.7. Parameters for Spreadsheet types (ods, xslm, xls, xlsx) .....	71
11.8. Parameters for HTML export .....	71
11.9. Compressing export files .....	72
11.10. Examples .....	72
12. Import data using WbImport .....	75
12.1. General parameters .....	75
12.2. Parameters for the type TEXT .....	80

---

12.3. Text Import Examples .....	83
12.4. Parameters for the type XML .....	86
12.5. Update mode .....	86
13. Copy data across databases .....	88
13.1. General parameters for the WbCopy command. ....	88
13.2. Copying data from one or more tables .....	89
13.3. Copying data based on a SQL query .....	91
13.4. Update mode .....	91
13.5. Synchronizing tables .....	91
13.6. Examples .....	92
14. Other SQL Workbench/J specific commands .....	94
14.1. Create a report of the database objects - WbSchemaReport .....	94
14.2. Compare two database schemas - WbSchemaDiff .....	95
14.3. Compare data across databases - WbDataDiff .....	96
14.4. Search source of database objects - WbGrepSource .....	99
14.5. Search data in multiple tables - WbGrepData .....	100
14.6. Define a script variable - WbVarDef .....	101
14.7. Delete a script variable - WbVarDelete .....	101
14.8. Show defined script variables - WbVarList .....	101
14.9. Confirm script execution - WbConfirm .....	101
14.10. Run a stored procedure with OUT parameters - WbCall .....	101
14.11. Execute a SQL script - WbInclude (@) .....	103
14.12. Extract and run SQL from a Liquibase ChangeLog - WbRunLB .....	104
14.13. Handling tables or updateable views without primary keys .....	104
14.14. Change the default fetch size - WbFetchSize .....	105
14.15. Run statements as a single batch - WbStartBatch, WbEndBatch .....	106
14.16. Extracting BLOB content - WbSelectBlob .....	106
14.17. Control feedback messages - WbFeedback .....	107
14.18. Setting connection properties - SET .....	107
14.19. Changing read only mode - WbMode .....	107
14.20. Show table structure - DESCRIBE .....	108
14.21. List tables - WbList .....	108
14.22. List stored procedures - WbListProcs .....	108
14.23. List triggers - WbListTriggers .....	109
14.24. Show the source of a stored procedures - WbProcSource .....	109
14.25. List catalogs - WbListCat .....	109
14.26. List schemas - WbListSchemas .....	109
14.27. Change the connection for a script - WbConnect .....	109
14.28. Run an XSLT transformation - WbXslt .....	110
14.29. Using Oracle's DBMS_OUTPUT package .....	111
15. DataPumper .....	112
15.1. Overview .....	112

# 1. General Information

## 1.1. Software license

Copyright (c) 2002-2010, Thomas Kellerer

Permission is hereby granted, free of charge, to any person obtaining a copy of this software and associated documentation files (the "Software"), to deal in the Software without restriction, including without limitation the rights to use, copy, publish, distribute, and to permit persons to whom the Software is furnished to do so, subject to the following conditions:

The above copyright notice and this permission notice shall be included in all copies or substantial portions of the Software.

The source code or parts of the source-code may only be reused with the permission of the author

In order to ensure that this software stays free, selling, licensing or charging for the use of this software is prohibited. The right to include this software in a commercial product (bundling) is still granted as long as this software is not the major functionality delivered.

### Disclaimer

The software is provided "as is", without warranty of any kind, express or implied, including but not limited to the warranties of merchantability, fitness for a particular purpose and noninfringement. In no event shall the author (Thomas Kellerer), be liable for any direct, indirect, incidental, special, exemplary, or consequential damages (including, but not limited to, procurement of substitute goods or services; loss of use, data, or profits; or business interruption) however caused and on any theory of liability, whether in contract, strict liability, or tort (including negligence or otherwise) arising in any way out of the use of this software, even if advised of the possibility of such damage.

In other words: use it at your own risk, and don't blame me if you accidentally delete your database!

## 1.2. Program version

This document describes build 110 of SQL Workbench/J

## 1.3. Feedback and support

Feedback regarding this program is more than welcome. Please report any problems you find, or send your ideas to improve the usability to: <support@sql-workbench.net>

SQL Workbench/J can be downloaded from <http://www.sql-workbench.net>

If you want to contact other users of SQL Workbench/J you can do this using an online forum at Google Groups: <http://groups.google.com/group/sql-workbench>

## 1.4. Credits and thanks

Thanks to Christian (and his team) for his thorough testing, his patience and his continuous ideas to improve this tool. His input has influenced and driven a lot of features and has helped reduce the number of bugs drastically!

## 1.5. Third party components

### 1.5.1. JLine

SQL Workbench/J includes the [JLine](#) library to support command line editing for the [console mode](#) on Unix style operating systems. The JDK on Windows supports full editing of the commandline including the usual Windows hotkeys to show the list of commands, so JLine is not used when SQL Workbench/J is running under Windows.

The copyright notice for JLine follows:

Copyright (c) 2002-2006, Marc Prud'hommeaux <mwp1@cornell.edu> All rights reserved.

Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met:

- Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer.
- Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution.
- Neither the name of JLine nor the names of its contributors may be used to endorse or promote products derived from this software without specific prior written permission.

THIS SOFTWARE IS PROVIDED BY THE COPYRIGHT HOLDERS AND CONTRIBUTORS "AS IS" AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE COPYRIGHT OWNER OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

### 1.5.2. Icons

Some icons are taken from Tango project: [http://tango.freedesktop.org/Tango\\_Icon\\_Library](http://tango.freedesktop.org/Tango_Icon_Library)

Some icons are taken from KDE Crystal project: <http://www.everaldo.com/crystal/>

The DbExplorer icon is from the icon set "Mantra" by Umar Irshad: <http://umar123.deviantart.com/>

## 2. Change log

Changes from build 109 to build 110

### Enhancements

- The (self-written) Windows launcher has been dropped and replaced with executables from Winrun4J, including support for 64bit executables (thanks to Markus for testing this).
- EXPLAIN is now supported for auto-completion (PostgreSQL, Oracle, MySQL)
- The DbExplorer will now show the status of Oracle stored procedures.
- The DbExplorer now includes information about partitioned tables and indexes for Oracle in the generated source.
- The possibility to influence the generated INSERT statement for WbImport is now available as a commandline parameter (previously this was only possible through a property in workbench.settings).
- Two new options for the SQL Formatter are available that control the placement of the comma when line breaks are inserted. Thanks to Andreas for this patch.
- The option "Allow empty line as statement delimiter" has been moved into the settings dialog and is now also being used when detecting the current statement in the editor.
- The font size of the editor can now be changed dynamically using Ctrl-Numpad Plus/Ctrl-Numpad Minus or via the scroll wheel of the mouse (holding down the Ctrl Key). The font size of a result table can be changed using the scroll wheel or through the context menu in the table header.
- It is now (optionally) possible to modify the text in the editor while a statement is running. Statement and error highlighting will not be available if the editor contents was modified during execution.
- When the option "Show Max. Rows warning" is enabled, the warning is now shown using an icon in the tab header (instead of changing the color).
- The join condition inside a JOIN part of a SELECT statement can now be generated automatically (if the tables involved are using foreign keys) using SQL -> JOIN completion
- Primary key columns are now shown in bold face in the auto-completion popup window. If comments are defined for columns, tables or view, these will be shown as a tooltip for the entry in the popup
- A new parameter -skipTargetCheck is available for WbCopy to disable checking of the target table. This is useful if the target table is not visible by the JDBC driver (e.g. temporary tables for Informix)
- A new parameter (-tableType) is available for WbCopy to control what kind of table is created when using -createTarget. The parameter value selects a SQL "template" that is defined in workbench.settings
- When using WbExport and -quoteAlways=true, null values are no longer escaped. The parameter can now be use with WbImport to distinguish between null values and empty strings.
- The escaping of embedded quotes can now also be selected when using "Save Data as" or "Import file".
- When connected to an Excel Spreadsheet, [] are now also recognized as quote characters (to allow a semicolon in a "table" name).
- The JDBC driver templates can now be loaded from an external file named "DriverTemplates.xml" that has to be stored in the directory where the jar file is located.
- When starting the console mode without specifying a password or when using a profile without a password, the application now prompts to enter a password

- A new option "Connection Timeout" has been added to the connection profiles.
- A new option to log all executed SQL statements to the logfile has been added (Tools -> Options -> General -> Log all SQL statements).
- The DataPumper now remembers the settings for importing text or XML files
- A new SQL formatter option has been added, to insert a space after a comma when processing IN (...) lists.
- The "Delete data" dialog in the DbExplorer now correctly commits for DBMS where TRUNCATE is transaction safe. The CASCADE option for PostgreSQL is also supported.

## Bug fixes

- Changing the font size in the editor would corrupt the display of the caret
- When exporting data, two tabs could not be defined as a separator (only a single tab)
- Oracle Procedures with the status "INVALID" were not shown in the DbExplorer
- The JOIN completion did not always detect the FKs correctly.
- Cancelling an import did not rollback the changes.
- When reloading the table list in the DbExplorer while "editing" mode was active, the table list was not retrieved correctly.
- Using WbCopy with schema qualified table names did not work properly when the target connection was using a different default schema.
- The rowcount in the statusbar was not always showing the correct values when more than one result was present
- JOIN completion did not work
- WbCall did not work for functions that were using OUT parameters
- When using a query as the source for WbCopy that used column aliases between databases that store object names in different case a wrong insert or update statement was created
- When changing the current database, the object cache was not updated correctly
- "Filter by selected value" did not work for boolean columns
- For PostgreSQL, columns defined as bit(x) with  $x > 1$  were not displayed correctly.
- When running a statement there was a built-in limit on 15 warnings that would be displayed by SQL Workbench. That limited the output of messages with RAISE NOTICE to 15 as well in PostgreSQL.
- The datatype for parameters in Oracle stored procedures was not always displayed correctly.
- When selecting JdbcOdbc bridge as the Driver class, SQL Workbench incorrectly showed an error message that the driver could not be found.
- Copying a table's column definitions into the clipboard did not work.
- When using WbCopy and -createTarget with a fully qualified table name (otherschema.sometable) the table was not created in the specified schema
- Postgres DOMAINS were not displayed if the DOMAIN was created in a schema that is not in the schema search\_path

- A selection of '\*' in the DbExplorer's schema selector was not restored if "Remember DbExplorer schema" was enabled for the workspace
- -quoteCharEscaping=duplicate was not working for WbImport if a quote character other than " was used.
- Procedures were no longer displayed in DbExplorer for DB2.
- A workaround for an Oracle driver bug was implemented, where the datatype for TIMESTAMP(3) was reported incorrectly.
- The generated XML content was not valid for ODS or OpenXML export if the generating SQL contained characters that needed escaping in XML.
- Statements were not closed properly when retrieving Oracle Object type information.
- Oracle RAW columns were not displayed correctly if the automatic data conversion was turned on.
- Using WbDataDiff (and WbSchemaDiff) with the -referenceSchema parameter or selecting specific tables for comparison did not work.
- Optimize column width calculated a width that was too wide (and increased with the total number of columns)
- When using the DataPumper to import xml files, non-standard column names were not quoted properly in the UPDATE statement
- When saving and loading the same file an empty line was appended each time the file was loaded.
- The console interface was no longer working.
- Importing multiple zipped text files into tables with BLOB columns did not work when using a batch size > 1
- When copying data to the clipboard, the data was always copied in the column order as retrieved from the database. If the column order was changed, this was not reflected in the copied data
- If a stored procedure in Oracle with the same name existed as a standalone procedure and a packaged procedure, the procedure columns for the standalone procedure were not displayed correctly in the DbExplorer
- When using the new lobPerDirectory parameter for WbExport, the directory numbering did not restart with a new table.
- WbSchemaReport created invalid SQL if column names contained characters that needed a replacement with an XML entity.

The full release history is available at the SQL Workbench/J [homepage](#)

## 3. Installing and starting SQL Workbench/J

### 3.1. Pre-requisites

To run SQL Workbench/J a [Java 6 runtime environment](#) is required. You can either use a JRE ("Runtime") or a JDK ("Development Kit") to run SQL Workbench/J.

### 3.2. First time installation

Once you have downloaded the application's distribution package, unzip the archive into a directory of your choice. Apart from that, no special installation procedure is needed.

You will need to configure the necessary JDBC driver(s) for your database before you can connect to a database. Please refer to the chapter [JDBC Drivers](#) for details on how to make the JDBC driver available to SQL Workbench/J

When starting SQL Workbench/J for the first time, it will create a directory called `.sqlworkbench` in the current user's home folder to store all its configuration information.

The "user's home directory" is `$HOME` on a Linux or Unix based system, and `%HOMEPATH%` on a Windows system. (Technically speaking it is using the contents of Java system property `user.home` to find the user's home directory)

### 3.3. Upgrade installation

When upgrading to a newer version of SQL Workbench/J simply overwrite the old `sqlworkbench.jar` and the exe launcher and shell scripts that start the application.

Starting with build 99 the file names have changed. The jar file is now named `sqlworkbench.jar` and the filename of the Windows launcher is now `sqlworkbench.exe`.

If you are upgrading from build 98 or earlier, please delete the old files `Workbench.jar` and `JWorkbench.exe`.

### 3.4. Starting the program from the commandline

`sqlworkbench.jar` is a self executing JAR file. This means, that if your JDK is installed properly, a double click (on the Windows® platform) on `sqlworkbench.jar` will execute the application. To run the application manually use the command:

```
java -jar sqlworkbench.jar
```

Native executables for Windows and Mac OSX are supplied that start SQL Workbench/J by using the default Java runtime installed on your system. Details on using the [Windows launcher](#) can be found [here](#).

### 3.5. Starting the program using the shell script

To run SQL Workbench/J under an Unix-type operating system, the supplied shell script `sqlworkbench.sh` can be used. For Linux desktops a sample ".desktop" file is available.

#### 3.5.1. Specifying the Java runtime for the shell script

The shell scripts (and the batch files) first check if the environment variable `WORKBENCH_JDK` is defined. If that variable is defined, the shell script will use `$WORKBENCH_JDK/bin/java` to run the application.

If `WORKBENCH_JDK` is not defined, the shell script will check for the environment variable `JAVA_HOME`. If that is defined, the script will use `$JAVA_HOME/bin/java` to run the application.

If neither `WORKBENCH_JDK` nor `JAVA_HOME` is defined, the shell script will simply use `java` to start the application, assuming that a valid Java runtime is available on the path.

All parameters that are passed to the shell scripts are passed to the application, not to the Java runtime. If you want to change the memory or other system settings for the JVM, you need to edit the shell script.

## 3.6. Starting the program using the Windows launcher

On a 32bit Windows® platform the supplied `SQLWorkbench.exe` can be used to start the program when using a Sun JDK. The native launcher searches for an installed JDK (querying the registry) and then starts SQL Workbench/J. The file `sqlworkbench.jar` has to be located in the same directory as the `SQLWorkbench.exe`, otherwise it doesn't work.

For a Windows 64bit system, you have to use `SQLWorkbench64.exe`. It will automatically search for a 64bit Java installation.

The launcher only works with a Sun JDK, as it directly calls the JDK's `dll` to start the virtual machine. If you are using a different JDK you cannot use the launcher to start SQL Workbench/J on Windows (unless it uses the same directory layout and filenames as the Sun JDK).

By default the launcher increases the maximum JVM heap size to 256MB. If you need more heap memory, you need to pass the appropriate JVM parameter to the launcher. Please refer to [Increasing the memory](#) for details on how to increase the memory that is available to SQL Workbench/J

### 3.6.1. Parameters for the Windows launcher

The launcher executables are based on [WinRun4J](#), further documentation on the format of the configuration file and parameters can also be found there.

## 3.7. Configuration directory

The configuration directory is the directory where all config (`workbench.settings`, `WbProfiles.xml`, `WbDrivers.xml`) files are stored.

If no configuration directory has been specified on the commandline, SQL Workbench/J will identify the configuration directory by looking at the following places

1. The current directory
2. The directory where `sqlworkbench.jar` is located
3. In the user's home directory (e.g. `$HOME/.sqlworkbench` on Unix based systems or `%HOMEPATH%\sqlworkbench` on Windows systems)

If the file `workbench.settings` is found in one of those directories, that directory is considered the configuration directory.

If no configuration directory can be identified, it will be created in the user's home directory (as `.sqlworkbench`).

The above mentioned search can be overridden by supplying the configuration directory [on the commandline](#) when starting the application.

Note that, before Build 98 the default configuration directory was the program's directory and not a directory in the user's home directory.

The following files are stored in the configuration directory:

- General configuration settings (`workbench.settings`)
- Connection profiles (`WbProfiles.xml`)
- JDBC Driver definitions (`WbDrivers.xml`)
- Customized shortcut definitions (`WbShortcuts.xml`). If you did not customize any of the shortcuts, this file does not exist
- Macro definitions (`WbMacros.xml`)
- Log file (`workbench.log`)
- Workspace files (`*.wksp`)

If you want to use a different file for the connection profile than `WbProfiles.xml` then you can specify the location of the profiles with the `-profilestorage` parameter on the commandline. Thus you can create different shortcuts on your desktop pointing to different sets of profiles. The different shortcuts can still use the same main configuration file.

### 3.7.1. Specifying the location of the configuration directory

If you want to control the location where SQL Workbench/J stores the configuration files, you have to start the application with the parameter `-configDir` to specify an alternate directory:

```
java -jar sqlworkbench.jar -configDir=/export/configs/SQLWorkbench
```

or if you are using the Windows® launcher:

```
SQLWorkbench -configDir=c:\ConfigData\SQLWorkbench
```

The placeholder `${user.home}` will be replaced with the current user's home directory (as returned by the Operating System), e.g.:

```
java -jar sqlworkbench.jar -configDir=${user.home}/.sqlworkbench
```

If the specified directory does not exist, it will be created.

To copy an installation to a different computer, simply copy all the above files to the other computer (the log file does not need to be copied). When a profile is connected to a workspace, the filename of the workspace file is usually stored with a placeholder for the configuration directory (`%configDir%`) so that the profiles don't need to be adjusted.

You will need to edit the driver definitions (stored in `WbDrivers.xml`) as the full path to the driver's jar file(s) is stored in the file (unless you define the location of the drivers using the [libdir variable](#)).

## 3.8. Increasing the memory available to the application

SQL Workbench/J is a Java application and thus runs inside a virtual machine (JVM). The virtual machine limits the memory of the application independently from the installed memory that is available to the operating system.

SQL Workbench/J reads the data that is returned by a `SELECT` statement into the main memory. When retrieving large result sets, you might get an error message, indicating that not enough memory is available. In this case you need to increase the memory that the JVM requests from the operating system (or change your statement to return fewer rows).

When you use the Windows® [Launcher](#) to start SQL Workbench/J you need to create a configuration file named `SQLWorkbench.ini` (or `SQLWorkbench64.ini` when using the 64bit launcher) with the following content:

```
vm.heapsize.preferred=512
```

This will increase the memory for the application to 512MB. For more options to configure the JVM, please refer to the documentation of [WinRun4J](#)

If you are running SQL Workbench/J on a non-Windows® operating system or do not want to use the launcher, then you need to pass this parameter directly to the JVM

```
java -Xmx512m -jar sqlworkbench.jar
```

If you are using the supplied shell scripts to start SQL Workbench/J, you can edit the scripts and change the value for the `-Xmx` parameter in there.

### 3.9. Command line parameters

Command line parameters are **not** case sensitive. The parameters `-PROFILE` or `-profile` are identical. The usage of the command line parameters is identical between the launcher or starting SQL Workbench/J using the `java` command itself.

When quoting parameters on the commandline (especially in a Windows environment) you have to use single quotes, as the double quotes won't be passed to the application.

#### 3.9.1. Specify the directory for configuration settings

The parameter `-configDir` specifies the directory where SQL Workbench/J will store all its settings. If this parameter is not supplied, the directory where the [default location](#) is used. The placeholder `${user.home}` will be replaced with the current user's home directory (as returned by the Operating System). If the specified directory does not exist, it will be created.

```
java -jar sqlworkbench.jar -configDir=${user.home}/wbconfig
SQLWorkbench -configDir='c:\Configurations\SQLWorkbench'
```

On the Windows platform you can use a forward slash to separate directory names in the parameter.

#### 3.9.2. Specify a base directory for JDBC driver libraries

The `-libdir` parameter defines the base directory for your JDBC drivers. The value of this parameter can be referenced when [defining a driver library](#) using the placeholder `%LibDir%`. The value for this parameter can also be set in the file [workbench.settings](#).

#### 3.9.3. Specify the file containing connection profiles

SQL Workbench/J stores the connection profiles in a file called `WbProfiles.xml`. If you want to use a different filename, or use different set of profiles for different purposes you can define the file where the profiles are stored with the `-profilestorage` parameter.

If the value of the parameter does not contain a path, the file will be expected (and stored) in the configuration directory.

### 3.9.4. Defining variables

With the `-vardef` parameter a definition file for [internal variables](#) can be specified. Each variable has to be listed on a single line in the format `variable=value`. Lines starting with a `#` character are ignored (comments). the file can contain unicode sequences (e.g. `\u00fc`). Values spanning multiple lines are not supported. When reading a file during startup the default encoding is used. If you need to read the file in a specific encoding please use the [WbVarDef](#) command with the `-file` and `-encoding` parameter.

```
#Define some values
var_id=42
person_name=Dent
another_variable=24
```

If the above file was saved under the name `vars.txt`, you can use those variables by starting SQL Workbench/J using the following commandline:

```
java -jar sqlworkbench.jar -vardef=vars.txt
```

You can also define a list of variables with this parameter. In this case, the first character after the `=` sign, has to be `#` (hash sign) to flag the value as a variable list:

```
java -jar sqlworkbench.jar -vardef=#var_id=42,person_name=Dent
```

Defining variable values in this way can also be used when running in [batch mode](#).

### 3.9.5. Prevent updating the .settings file

If the `-nosettings` parameter is specified, SQL Workbench/J will not write its settings to the file `workbench.settings` when it's been closed. Note that in [batch mode](#), this file is never written.

If this parameter is supplied, the workspace will not be saved automatically as well!

### 3.9.6. Connect using a pre-defined connection profile

You can specify the name of an already created [connection profile](#) on the commandline with the `-profile=<profile name>` parameter. The name has to be passed exactly like it appears in the profile dialog (case sensitiv!). If the name contains spaces or dashes, it has to be enclosed in quotations marks. If you have more than one profile with the same name but in different profile groups, you have to specify the desired profile group using the `-profilegroup` parameter, otherwise the first profile matching the passed name will be selected.

Example (on one line):

```
java -jar sqlworkbench.jar
  -profile='PostgreSQL - Test'
  -script='test.sql'
```

In this case the file `WbProfiles.xml` must be in the current (working) directory of the application. If this is not the case, please specify the location of the profile using either the [-profilestorage](#) or [-configDir](#) parameter.

If you have two profiles with the names "Oracle - Test" you will need to specify the profile group as well (in one line):

```
java -jar sqlworkbench.jar
```

```
-profile='PostgreSQL - Test'
-profilegroup='Local'
-script='test.sql'
```

### 3.9.7. Connect without a profile

You can also specify the full connection parameters on the commandline, if you don't want to create a profile only for executing a batch file. The advantage of this method is, that SQL Workbench/J does not need the files `WbProfiles.xml`, `WbDrivers.xml` to be able to connect to the database.

The connection can be specified with the following parameters:

Parameter	Description
-url	The JDBC connection URL
-username	Specify the username for the DBMS
-password	Specify the password for the user
-driver	Specify the full class name of the JDBC driver
-driverJar	Specify the full pathname to the .jar file containing the JDBC driver
-autocommit	Set the autocommit property for this connection. You can also control the autocommit mode from within your script by using the <a href="#">SET AUTOCOMMIT</a> command.
-rollbackOnDisconnect	If this parameter is set to true, a ROLLBACK will be sent to the DBMS before the connection is closed. This setting is also available in the <a href="#">connection profile</a> .
-trimCharData	Turns on right-trimming of values retrieved from CHAR columns. See the <a href="#">description</a> of the profile properties for details.
-removeComments	This parameter corresponds to the <a href="#">Remove comments</a> setting of the connection profile.
-fetchSize	This parameter corresponds to the <a href="#">Fetch size</a> setting of the connection profile.
-ignoreDropError	This parameter corresponds to the <a href="#">Ignore DROP errors</a> setting of the connection profile.
-emptyStringIsNull	This parameter corresponds to the <a href="#">Empty String is NULL</a> setting of the connection profile. This will only be needed when editing a result set in GUI mode.
-connectionProperties	<p>This parameter can be used to pass <a href="#">extended connection properties</a> if the driver does not support them e.g. in the JDBC URL. The values are passed as key=value pairs, e.g. <code>-connectionProperties=someProp=42</code></p> <p>If either a comma or an equal sign occurs in a parameter's value, it must be quoted. This means, when passing multiple properties the whole expression needs to be quoted: <code>-connectionProperties='someProp=42,otherProp=24'</code>.</p> <p>As an alternative, a colon can be used instead of the equals sign, e.g. <code>-connectionProperties=someProp:42,otherProp:24</code>. In this case no quoting is needed (because no delimiter is part of the parameters value).</p> <p>If any of the property values contain a comma or an equal sign, then the whole parameter value needs to be quoted again, even when using a colon. <code>-connectionProperties='someProp:"answer=42",otherProp:"2,4"'</code> will define the value <code>answer=42</code> for the property <code>someProp</code> and the value <code>2,4</code> for the property <code>otherProp</code>.</p>
-altDelim	The <a href="#">alternate delimiter</a> to be used for this connection. To define a single line delimiter append the characters <code>:nl</code> to the parameter value: e.g. <code>-altDelimiter=GO:nl</code> to define a SQL Server like GO as the alternate delimiter. Note that when running in batchmode you can also override the default delimiter by specifying the <a href="#">-delimiter</a> parameter.

Parameter	Description
-separateConnection	If this parameter is set to true, and SQL Workbench/J is run in GUI mode, each SQL tab will use it's own connection to the database server. This setting is also available in the <a href="#">connection profile</a> . The default is true.
-workspace	The workspace file to be loaded. If the file specification does not include a directory, the workspace will be loaded from the <a href="#">configuration directory</a> . If this parameter is not specified, the default workspace (Default.wksp) will be loaded.
-readOnly	Puts the connection into <a href="#">read-only mode</a> .

If a value for one of the parameters contains a dash or a space, you will need to quote the parameter value.

A disadvantage of this method is, that the password is displayed in plain text on the command line. If this is used in a batch file, the password will be stored in plain text in the batch file. If you don't want to expose the password, you can use a connection profile and [enable password encryption](#) for connection profiles.

## 4. JDBC Drivers

### 4.1. Configuring JDBC drivers

Before you can connect to a DBMS you have to configure the JDBC driver to be used. The driver configuration is available in the connection dialog or through File » Manage Drivers

The configuration of a specific driver requires at least two properties:

- the driver's class name
- the library ("JAR file") where to find the driver class

After you have selected the .jar file for a driver, SQL Workbench/J will scan the jar file looking for a JDBC driver. If only a single driver is found, the classname is automatically put into the entry field. If more than one class is found that is a driver implementation, you will be prompted to select one. In that case, please refer to the manual of your driver, to choose the correct one.

If you enter the class name of the driver manually, remember that it's case-sensitive.

`org.postgresql.driver` is different to `org.postgresql.Driver` (note the capital D for Driver)

The name of the library has to contain the full path to the driver's jar file, so that SQL Workbench/J can find it. Some drivers are distributed in several jar files. In that case, select all necessary files in the file open dialog, or enter all the filenames separated by a semicolon (or a colon on Unix style operating systems). This is also true for drivers that require a license file that is contained in a jar file. In this case you have to include the license jar in the list of files. Basically this list defines the classpath for the classloader that is used to load and instantiate the driver.

If the driver accesses files through its classpath definition that are not contained in a jar library, you have to include that directory as part of the library definition (e.g: "`c:\etc\TheDriver\jdbcDriver.jar;c:\etc\TheDriver`"). The file selection dialog will not let you select a directory, so you have to add it manually to the library definition.

SQL Workbench/J is **not** using the system CLASSPATH definition (i.e. environment variable) to load the driver classes. Changing the CLASSPATH environment variable to include your driver's library will not work. Using the `-cp` switch to add a driver to the classpath when starting the application through a batch file will also not work.

You do not need to specify a library for the JDBC-ODBC bridge, as the necessary drivers are already part of the Java runtime.

You can assign a sample URL to each driver, which will be put into the URL property of the profile, when the driver class is selected.

SQL Workbench/J comes with some sample URLs pre-configured. Some of these sample URLs use brackets to indicate a parameters that need to be replaced with the actual value for your connection: (servername) In this case the entire sequence including the brackets need to be replaced with the actual value.

### 4.2. Connecting through ODBC

To connect to a database using an ODBC driver, you must first setup an ODBC datasource with the tools of your operating system (e.g. the control panel in Windows®)

Once you have set up the ODBC datasource, select the ODBC Bridge as the driver in the connection dialog. The JDBC URL for the datasource connection then is `jdbc:odbc:name_of_your_datasource`.

If you named your ODBC datasource `ProductDB`, then the JDBC url for SQL Workbench/J would be `jdbc:odbc:ProductDB`

### 4.3. Specifying a library directory

When defining the location of the driver's .jar file, you can use the placeholder %LibDir% instead of the using the directory's name directly. This way your WbDrivers.xml is portable across installations. To specify the library directory, either set it in the [workbench.settings](#) file, or specify the directory using the [-libdir](#) switch when starting the application.

### 4.4. Popular JDBC drivers

Here is an overview of common JDBC drivers, and the classname that need to be used. SQL Workbench/J contains predefined JDBC drivers with sample URLs for connecting to the database.

Most drivers accept additional configuration parameters either in the URL or through the [extended properties](#). Please consult the manual of your driver for more detailed information on these additional parameters.

DBMS	Driver class	Library name
PostgreSQL	org.postgresql.Driver	postgresql-8.4-701.jdbc4.jar (exact name depends on PostgreSQL version) <a href="http://jdbc.postgresql.org">http://jdbc.postgresql.org</a>
Firebird SQL	org.firebirdsql.jdbc.FBDriver	firebirdsql-full.jar <a href="http://www.firebirdsql.org/">http://www.firebirdsql.org/</a>
Oracle	oracle.jdbc.OracleDriver	ojdbc6.jar <a href="http://www.oracle.com/technetwork/database/features/jdbc/index-091264.html">http://www.oracle.com/technetwork/database/features/jdbc/index-091264.html</a>
H2 Database Engine	org.h2.Driver	h2.jar <a href="http://www.h2database.com">http://www.h2database.com</a>
HSQLDB	org.hsqldb.jdbcDriver	hsqldb.jar <a href="http://hsqldb.sourceforge.net">http://hsqldb.sourceforge.net</a>
IBM DB2	com.ibm.db2.jcc.DB2Driver	db2jcc4.jar <a href="http://www-01.ibm.com/support/docview.wss?rs=4020&amp;uid=swg21385217">http://www-01.ibm.com/support/docview.wss?rs=4020&amp;uid=swg21385217</a>
IBM DB2 for iSeries	com.ibm.as400.access.AS400JDBCDriver	jt400.jar <a href="http://www-01.ibm.com/software/data/db2/java/">http://www-01.ibm.com/software/data/db2/java/</a>
Apache Derby	org.apache.derby.jdbc.EmbeddedDriver	derby.jar <a href="http://db.apache.org/derby/">http://db.apache.org/derby/</a>
Teradata	com.teradata.jdbc.TeraDriver	terajdbc4.jar <a href="http://www.teradata.com/DownloadCenter/Forum158-1.aspx">http://www.teradata.com/DownloadCenter/Forum158-1.aspx</a>
Sybase SQL Anywhere	com.sybase.jdbc3.jdbc.SybDriver	jconnect.jar <a href="http://www.sybase.com/products/allproductsa-z/softwaredeveloperkit/jconnect">http://www.sybase.com/products/allproductsa-z/softwaredeveloperkit/jconnect</a>
MySQL	com.mysql.jdbc.Driver	mysql-connector-java-5.1.5-bin.jar (exact name depends on version) <a href="http://www.mysql.com">http://www.mysql.com</a>
SQL Server 2000/2005 (Microsoft driver)	com.microsoft.sqlserver.jdbc.SQLServerDriver	sqljdbc4.jar <a href="http://www.microsoft.com/sqlserver/2005/en/us/java-database-connectivity.aspx">http://www.microsoft.com/sqlserver/2005/en/us/java-database-connectivity.aspx</a>
SQL Server (JTDS driver)	net.sourceforge.jtds.jdbc.Driver	jtds.jar <a href="http://jtds.sourceforge.net">http://jtds.sourceforge.net</a>

<b>DBMS</b>	<b>Driver class</b>	<b>Library name</b>
ODBC Bridge	sun.jdbc.odbc.JdbcOdbcDriver	Included in the JDK

## 5. Connecting to the database

### 5.1. Connection profiles

SQL Workbench/J uses the concept of profiles to store connection information. A connection profile stores two different types of settings:

- JDBC related properties such as the JDBC driver class, the connection URL, the username etc.
- SQL Workbench/J related properties such as the profile name the associated workspace, etc.

After the program is started, you are prompted to choose a connection profile to connect to a database. The dialog will display a list of available profiles on the left side. When selecting a profile, its details (JDBC and SQL Workbench/J settings) are displayed on the right side of the window.

To create a new profile click on the **New Profile** button (). This will create a new profile with the name "New Profile". The new profile will be created in the currently active group. The other properties will be empty. To create a copy of the currently selected profile click on the **Copy Profile** button (). The copy will be created in the current group. If you want to place the copy into a different group, you can either choose to **Copy & Paste** a copy of the profile into that group, or move the copied profile, once it is created.

To delete an existing profile, select the profile in the list and click on the **Delete Profile** button ().

### 5.2. Managing profile groups

Profiles can be organized in groups, so you can group them by type (test, integration, production) or customer or database system. When you start SQL Workbench/J for the first time, no groups are created and the tree will only

display the default group node. To add a new group click on the **Add profile group** () button. The new group will be appended at the end of the tree. If you create a new profile, it will be created in the currently selected group. If a profile is selected in the tree and not a group node, the new profile will be created in the group of the currently selected profile.

Empty groups are discarded (i.e. not saved) when you restart SQL Workbench/J

You can move profiles from one group to another but right clicking on the profile, then choose **Cut**. Then right-click on the target group and select **Paste** from the popup menu. If you want to put the profile into a new group that is not yet created, you can choose **Paste to new folder**. You will be prompted to enter the new group name.

If you choose **Copy** instead of **Cut**, a copy of the selected profile will be pasted into the target group. This is similar to copying the currently selected profile.

To rename a group, select the node in the tree, then press the F2 key. You can now edit the group name.

To delete a group, simply remove all profiles from that group. The group will then automatically be removed.

### 5.3. JDBC related profile settings

Property	Description
Driver	This is the classname for the JDBC driver. The exact name depends on the DBMS and driver combination. The documentation for your driver should contain this information. SQL Workbench/J has some drivers pre-configured. See JDBC drivers for details on how to configure your JDBC driver for SQL Workbench/J.
URL	The connection URL for your DBMS. This value is DBMS specific. The pre-configured drivers from SQL Workbench/J contain a sample URL. If the sample URL (which gets filled into the text field when you select a driver class) contains words in brackets, then these words (including the brackets) are placeholders for the actual values. You have to replace them (including the brackets) with the appropriate values for your DBMS connection.
Username	This is the name of the DBMS user account
Password	This is the password for your DBMS user account. You can choose not to store the password in the connection profile.
Autocommit	This checkbox enables/disables the property for the connection. If autocommit is enabled, then each SQL statement is automatically committed on the DBMS. If this is disabled, any DML statement (UPDATE, INSERT, DELETE, ...) has to be committed in order to make the change permanent. Some DBMS require a commit for DDL statements (CREATE TABLE, ...) as well. Please refer to the documentation of your DBMS.
Fetch size	<p>This setting controls the default fetch size for data retrieval. This parameter will directly be passed to the <a href="#">setFetchSize()</a> method of the Statement object. For some combinations of JDBC driver and DBMS, setting this parameter to a rather large number can improve retrieval performance because it saves network traffic.</p> <p>The <a href="#">JDBC driver</a> for <a href="#">PostgreSQL</a> controls the <a href="#">caching</a> of ResultSets through this parameter. As the results are cached by SQL Workbench/J anyway, it is suggested to set this parameter to a value greater than zero to disable the caching in the driver. Especially when exporting large results using <a href="#">WbExport</a> or <a href="#">WbCopy</a> it is recommended to turn off the caching in the driver (e.g. by setting the value for this property to 1).</p> <p>You can change the fetch size for the current connection manually by running the SQL Workbench/J specific command <a href="#">WbFetchSize</a></p>
Timeout	This property defines a timeout in seconds that is applied when establishing the connection to the database server. If no connection is possible in that time, the attempt will be aborted. If this is empty, the default timeout defined by the JDBC driver is used.

### 5.4. Extended properties for the JDBC driver

JDBC drivers support additional connection properties where you can fine tune the behaviour of the driver or enable special features that are not switched on by default. Most drivers support passing properties as part of the URL, but sometimes they need to be passed to the driver using a different method called extended properties.

If you need to pass an additional parameter to your driver you can do that with the Extended Properties button. After clicking that button, a dialog will appear with a table that has two columns. The first column is the name of the property, the second column the value that you want to pass to the driver.

To create a new property click on the new button. A new row will be inserted into the table, where you can define the property. To edit an existing property, simply doubleclick in the table cell that you want to edit. To delete an existing property click on the Delete button (✕).

Some driver require those properties to be so called "System properties" (see the manual of your driver for details). If this is the case for your driver, check the option `Copy to system properties` before connecting.

## 5.5. SQL Workbench/J specific settings

### 5.5.1. Save password

If this option is enabled (i.e. checked) the password for the profile will also be stored in the profile file. If the global option [Encrypt Passwords](#) is selected, then the password will be stored encrypted, otherwise it will be stored in plain text!

If you choose not to store the password, you will be prompted for it each time you connect using the profile.

### 5.5.2. Separate connection per tab

If this option is enabled, then each tab in the main window will open a separate (physical) connection to the database server. This is useful, if the JDBC driver is not multi-threaded and does not allow to execute two statements concurrently on the same connection.

The connection for each tab will not be opened until the tab is actually selected.

Enabling this option has impact on transaction handling as well. If only one connection for all tabs (including the [Database Explorer](#)) is used, then a transaction that is started in one tab is "visible" to all other tabs (as they share the same connection). Changes done in one tab via `UPDATE` are seen in all other tabs (including the Database Explorer). If a separate connection is used for each tab, then each tab will have its own transaction context. Changes done in one tab will not be visible in other tabs until they are committed (depending on the isolation level of the database of course)

If you intend to execute several statements in parallel then it's strongly recommended to use one connection for each tab. Most JDBC drivers are not multi-threaded and thus cannot run more then on statement on the same connection. SQL Workbench/J does try to detect conflicting usages of a single connection as far as possible, but it is still possible to lock the GUI when running multiple statements on the same connection

When you disable the use of separate connections per tab, you can still create new a (physical) connection for the current tab later, by selecting `File » New Connection`. That menu item will be disabled if `Separate connection per tab` is disabled or you have already created a new connection for that tab.

### 5.5.3. Ignore DROP errors

If this option is enabled, any error reported by the database server when issuing a statement that begins with `DROP`, will be ignored. Only a warning will be printed into the message area. This is useful when executing SQL scripts to build up a schema, where a `DROP TABLE` is executed before each `CREATE TABLE`. If the table does not exist the error which the `DROP` statement will report, is not considered as an error and the script execution continues.

When running SQL Workbench/J in batchmode this option can be defined using a separate command line parameter. See Section 9, "Using SQL Workbench/J in batch files" for details.

### 5.5.4. Rollback before disconnect

Some DBMS require that all open transactions are closed before actually closing the connection to the server. If this option is enabled, SQL Workbench/J will send a `ROLLBACK` to the backend server before closing the connection. This is e.g. required for Cloudscape/Derby because executing a `SELECT` query already starts a transaction. If you see errors in your log file while disconnecting, you might need to enable this for your database as well.

### 5.5.5. Confirm updates

If this option is enabled, then SQL Workbench/J will ask you to confirm the execution of any SQL statement that is updating or changing the database in any way (e.g. UPDATE, DELETE, INSERT, DROP, CREATE, COMMIT, ...).

If you save changes from within the result list, you will be prompted even if [Confirm result set updates](#) is disabled.

This option cannot be selected together with the "Read only" option.

The read only state of the connection can temporarily be changed (without modifying the profile) using the [WbMode](#) command.

### 5.5.6. Read only

If this option is enabled, then SQL Workbench/J will never run any statements that might change the database. Changing of retrieved data is also disabled in this case. This option can be used to prevent accidental changes to important data (e.g. a production database)

SQL Workbench/J cannot detect all possible statements that may change the database. Especially when calling stored procedures SQL Workbench/J cannot know if they will change the database. But they might be needed to retrieve data, this cannot be disabled altogether.

You can extend the list of keywords known to update the data in the [workbench.settings](#) file.

SQL Workbench/J will not guarantee that there is no way (accidentally or intended) to change data when this option is enabled. Please do not rely on this option when dealing with important data that must not be changed.

If you really need to guarantee that no data is changed, you have to do this with the security mechanism of your DBMS, e.g. by creating a read-only user.

This option cannot be selected together with the "Confirm updates" option.

The read only state of the connection can temporarily be changed (without modifying the profile) using the [WbMode](#) command.

### 5.5.7. Empty string is NULL

If this option is enabled, then a NULL value will be sent to the database for an empty (zero length) string. Everything else will be sent to the database as entered.

Empty values for non-character values (dates, numbers etc) are always treated as NULL.

If this option is disabled you can still set a column's value to NULL while editing a result set. Please see [Editing data](#) [43] for details

### 5.5.8. Include NULL columns in INSERT

This setting controls whether columns where the value from the result grid is null are included in INSERT statements. If this setting is enabled, then columns for new rows that have a null value are listed in the column list for the INSERT statement (with the corresponding NULL value passed in the VALUES list). If this property is un-checked, then those columns will not be listed in INSERT statements. This is useful if you have e.g. auto-increment columns that only work if the columns are not listed in the DML statement.

### 5.5.9. Remove comments

If this option is checked, then comments will be removed from the SQL statement before it is sent to the database. This covers single line comments using `--` or multi-line comments using `/* .. */`

As an ANSI compliant SQL Lexer is used for detecting comments, this does **not** work for non-standard MySQL comments using the # character.

#### 5.5.10. Hide warnings

When a SQL statement returns warnings from the DBMS, these are usually displayed after the SQL statement has finished. By enabling this option, warnings that are returned from the DBMS are never displayed.

Note that for some DBMS (e.g. MS SQL Server) server messages (PRINT 'Hello, world') are also returned as a warning by the driver. If you disable this property, those messages will also not be displayed.

If you hide warnings when connected to a PostgreSQL server, you will also not see messages that are returned e.g. by the VACUUM command.

#### 5.5.11. Remember DbExplorer Schema

If this option is enabled, the currently selected schema in the DbExplorer will be stored in the workspace associated with the current connection profile. If this option is not enabled, the DbExplorer tries to pre-select the current schema when it's opened.

#### 5.5.12. Trim CHAR data

For columns defined with the CHAR datatype, some DBMS pad the values to the length defined in the column definition (e.g. a CHAR(80) column will always contain 80 characters). If this option is enabled, SQL Workbench/J will remove trailing spaces from the values retrieved from the database. When running SQL Workbench/J in batch mode, this flag can be enabled using the `-trimCharData` switch.

#### 5.5.13. Info Background

Once a connection has been established, information about the connection are display in the toolbar of the main window. You can select a color for the background of this display to e.g. indicate "sensitive" connections. To use the default background, click on the Reset () button. If no color is selected this is indicated with the text (None) next to the selection button. If you have selected a color, a preview of the color is displayed.

#### 5.5.14. Alternate delimiter

If an alternate delimiter is defined, and the statement that is executed ends with the defined delimiter, this one will be used instead of the standard semicolon. The profile setting will overwrite the global setting for this connection. This way you can define the GO keyword for SQL Server connections, and use the forward slash in Oracle connections. The delimiter can be defined as a "single line delimiter", which means that it will only be recognized if put on a single line. Please refer to [using the alternate delimiter](#) for details on this property.

#### 5.5.15. Workspace

For each connection profile, a workspace file can (and should) be assigned. When you create a new connection, you can either leave this field empty or supply a name for a new profile.

If the profile that you specify does not exist, you will be prompted if you want to create a new file, load a different workspace or want to ignore the missing file. If you choose to ignore, the association with the workspace file will be cleared and the default workspace will be loaded.

If you choose to leave the workspace file empty, or ignore the missing file, you can later save your workspace to a new file. When you do that, you will be prompted if you want to assign the new workspace to the current connection profile.

To save your current workspace choose **Workspace » Save Workspace as** to create a new workspace file.

When specifying the location of the workspace file, you can use the placeholder `%ConfigDir%` as part of the filename. The file will then be stored in the same directory as SQL Workbench/J's [configuration files](#) e.g.: `%ConfigDir%/oracle.wksp`

When you use the `%ConfigDir%` placeholder, you can move the profiles and workspaces to a different computer, without changing the location of the workspace files.

The placeholder will be put automatically into the filename when you select the location of the profile using the file dialog. The file dialog will be opened when you click the button with `...` to the right of the input field.

As the workspace stores several settings that are related to the connection (e.g. the selected schema in the [DbExplorer](#)) it is recommended to create one workspace for each connection profile.

### 5.5.16. Connect scripts

You can define a SQL script that is executed immediately after a connection for this profile has been established, and a script that is executed before a connection is about to be closed. To define the scripts, click on the button **Connect scripts**. A new window will be opened that contains two editors. Enter the script that should be executed upon connecting into the upper editor, the script to be executed before disconnecting into the lower editor. You can put more than one statement into the scripts. The statements have to be separated by a semicolon.

The statements that are executed will be logged in the message panel of the SQL panel where the connection is created. You will not see the log when a connection for the DbExplorer is created.

Execution of the script will stop at the first statement that throws an error. The error message will also be logged to the message panel. If the connection is made for a DbExplorer panel, the errors will only be visible in the log file.

### Keep alive script

Some DBMS are configured to disconnect an application that has been idle for some time. You can define an idle time and a SQL statement that is executed when the connection has been idle for the defined interval. This is also available when clicking on the **Connect scripts**.

The keep alive statement can not be a script, it can only be a **single SQL** statement (e.g. `SELECT version()` or `SELECT 42 FROM dual`). You may not enter the trailing semicolon.

The idle time is defined in milliseconds, but you can also enter the interval in seconds or minutes by appending the letter 's' (for seconds) or 'm' (for minutes) to the value. e.g.: `30000` (30 seconds), or `45s` (45 seconds), or `10m` (10 minutes).

You can disable the keep alive feature by deleting the entry for the interval but keeping the SQL statement. Thus you can quickly turn off the keep alive feature but keep the SQL statement for the next time.

### 5.5.17. Schema and Catalog filters

If your database contains a lot of schema or catalogs that you don't want to be listed in the dropdown of the [DbExplorer](#), you can define filter expressions to hide certain entries.

The filters are defined by clicking on the **Schema/Catalog Filter** button. The filter dialog contains two input fields, one to filter schema name and one to filter catalog names.

Each line of the filter definition defines a single regular expression of schema/catalog names to be *excluded* from the dropdown, i.e. if a schema/catalog matches the defined name, it will not be listed in the dropdown.

The filter items are treated as regular expressions, so the standard SQL wildcards will not work here. The basic expression is just a name (e.g. `MDSYS`). Comparison is always done case-insensitive. So `mdsys` and `MDSYS` will achieve the same thing.

If you want to filter all schemas that start with a certain value, the regular expression would be: `^pg_toast.*`. Note the dot followed by a `*` at the end. In a regular expression the dot matches any character, and the `*` will allow any number of characters to follow. The `^` specifies that the whole string must occur at the beginning of the value.

The regular expression must match completely in order to exclude the value from the dropdown.

If you want to learn more about regular expressions, please have a look at <http://www.regular-expressions.info/>

## 5.6. Connect to Oracle with SYSDBA privilege

Connecting to Oracle with SYSDBA privilege can be done by supplying an additional property to the driver when connecting.

In the profile dialog, click on the Extended Properties button. Add a new property in the following window with the name `internal_logon` and the value `sysdba`. Now close the dialog by clicking on the OK button. This property will be passed on to the JDBC driver, which will enable the SYSDBA role when connecting to the server.

The profile itself has to use an Oracle user account that is allowed to connect as SYSDBA (e.g. SYS).

## 5.7. ODBC connections without a data source

On Microsoft Windows® you can use the ODBC bridge to connect to ODBC datasources. For some drivers you don't need to create an ODBC datasource in order to be able to use the ODBC driver. The following URLs can be used to connect to data files directly.

The class name of the driver is `sun.jdbc.odbc.JdbcOdbcDriver`

ODBC Connection	URL to be used
Excel	<code>jdbc:odbc:DRIVER={Microsoft Excel Driver (*.xls)};DBQ=&lt;filename&gt;</code>
Access	<code>jdbc:odbc:DRIVER={Microsoft Access Driver (*.mdb)};DBQ=&lt;filename&gt;</code>
dBase	<code>jdbc:odbc:DRIVER={Microsoft dBase Driver (*.dbf)};DefaultDir=&lt;directory where the .dbf files are located&gt;</code>

## 6. Editing SQL Statements

### 6.1. Editing files

You can load and save the editor's content into external files (e.g. for re-using) them in other SQL tools.

To load a file use File » Open... or right click on the tab's label and choose Open... from the popup menu.

The association between an editor tab and the external file will be saved in the workspace that is used for the current connection. When opening the workspace (e.g. by connecting using a profile that is linked to that workspace) the external file will be loaded as well.

If you want to run very large SQL scripts (e.g. over 15MB) it is recommended to execute them using [WbInclude](#) rather than loading them completely into the editor. `WbInclude` will not load the script into memory, thus you can even run scripts that would not fit into memory.

### 6.2. Command completion

The editor can show a popup window with a list of available tables (and views) or a list of available columns for a table. Which list is displayed depends on the position of the cursor inside the statement.

If the cursor is located in the column list of a `SELECT` statement and the `FROM` part already contains the necessary tables, the window will show the columns available in the table. Assuming you are editing the following statement ( the | indicating the position of the caret):

```
SELECT p.|, p.firstname, a.zip, a.city
FROM person p
      JOIN address a ON p.id = a.person_id;
```

then pressing the **Ctrl-Space** key will show a list of columns available in the `PERSON` table (because the cursor is located after the `p.` alias). If you put the cursor after the `a.city` column and press the **Ctrl-Space** the popup window will list the two tables that are referenced in the `FROM` part of the statement. The behaviour when editing the `WHERE` part of an statement is similar.

When editing the list of tables in the `FROM` part of the statement, pressing the **Ctrl-Space** will pop up a list of available tables.

The editor assumes that the standard semicolon is used to separate statements when doing auto-completion or using the "Execute current" function. This can be changed to a non-standard behaviour through the [options dialog](#) so that the editor also recognizes empty lines as a statement delimiter.

Parameters for SQL Workbench/J specific commands are also supported by the command completion. The parameters will only be shown, if you have already typed the leading dash, e.g. `WbImport -`. If you press the shortcut for the command completion while the cursor is located after the dash, a list of available options for the current command is shown. Once the parameter has been added, you can display a list of possible values for the parameter if the cursor is located after the equals sign. for `WbImport -mode=` will display a list of allowed values for the `-mode` parameter. For parameters where table names can be supplied the usual table list will be shown.

### 6.3. JOIN completion

When using ANSI JOIN syntax to create table joins with tables linked by foreign keys in the database, the command `JOIN completion` can be used to automatically generate the necessary join condition. Consider the following statement

```
SELECT ord.amount, ord.order_date, prod.name
FROM orders ord
      JOIN product prod ON
```

When the cursor is located behind the `ON` keyword, and you select `SQL » JOIN` completion, SQL Workbench/J will retrieve the foreign key and corresponding primary key definitions between the tables `orders` and `product`. If such constraints exist, the corresponding condition will be generated and written into the editor. After executing JOIN completion, the SQL statement will look like this:

```
SELECT ord.amount, ord.order_date, prod.name
FROM orders ord
      JOIN product prod ON prod.id = ord.product_id
```

This feature depends on the usage of the `JOIN` keyword. Joining tables in the `WHERE` clause is not supported!

## 6.4. Customizing keyword highlighting

The keywords that the editor can highlight are based on an internal list of keywords and information obtained from the JDBC driver. You can extend the list of known keywords using text files located in the [config directory](#).

SQL Workbench/J reads four different types of keywords: regular keywords (e.g. `SELECT`), datatypes (e.g. `VARCHAR`), functions (e.g. `upper()`) and operators (e.g. `JOIN`). Each keyword type is read from a separate file: `keywords.wb`, `datatypes.wb`, `functions.wb` and `operators.wb`.

The files contain one keyword per line. Case does not matter (`SELECT` and `select` are treated identically). If you want to add a specific word to the list of global keywords, simply create a plain text file `keywords.wb` in the [config directory](#) and put one keyword per line into the file, e.g.:

```
ALIAS
ADD
ALTER
```

If you want to define keywords specific for a DBMS, you need to add the [DBID](#) as a prefix to the filename, e.g. `oracle.datatypes.wb`.

To add the word `geometry` as a datatype for the editor when connected to a PostgreSQL database, create the file `postgresql.datatypes.wb` in the config directory with the following contents:

```
geometry
```

The words defined for a specific database are added to the globally recognized keywords, so you don't need to repeat all existing words in the file.

The color for each type of keyword can be changed in the options dialog.

## 6.5. Reformat SQL

When you analyze statements from e.g. a log file, they are not necessarily formatted in a way that can be easily read, let alone understood. The editor of the SQL Workbench/J can reformat SQL statements into a format that's easier to read and understand for a human being. This feature is often called pretty-printing. Suppose you have the following statement (pasted from a log file)

```
select user.* from user, user_profile, user_data
where user.user_id = user_profile.user_id and
```

```
user_profile.user_id = uprof.user_id and user_data.user_role = 1
and user_data.delete_flag = 'F' and not exists
(select 1 from data_detail where data_detail.id = user_data.id and
data_detail.flag = 'X' and data_detail.value > 42)
```

this will be reformatted to look like this:

```
SELECT user.*
FROM user,
      user_profile,
      user_data
WHERE user.user_id = user_profile.user_id
AND   user_profile.user_id = uprof.user_id
AND   user_data.user_role = 1
AND   user_data.delete_flag = 'F'
AND   NOT EXISTS (SELECT 1
                  FROM data_detail
                  WHERE data_detail.id = user_data.id
                  AND   data_detail.flag = 'x'
                  AND   data_detail.value > 42)
```

You can configure a threshold up to which sub-SELECTs will not be reformatted but put into one single line. The default for this threshold is 80 characters. Meaning that any subselect that is shorter than 80 characters will not be reformatted as the sub-SELECT in the above example. Please refer to [Formatting options](#) for details.

## 6.6. Create SQL value lists

Sometimes when you Copy & Paste lines of text from e.g. a spreadsheet, you might want to use those values as a condition for a SQL IN expression. Suppose you have a list of ID's in your spreadsheet each in one row of the same column. If you copy and paste this into the editor, each ID will be put on a separate line. If you select the text, and then choose SQL » Create SQL List the selected text will be converted into a format that can be used as an expression for an IN condition:

```
Dent
Beeblebrox
Prefect
Trillian
Marvin
```

will be converted to:

```
('Dent',
 'Beeblebrox',
 'Trillian',
 'Prefect',
 'Marvin')
```

The function SQL » Create non-char SQL List is basically the same. The only difference is, that it assumes that each item in the list is a numeric value, and no single quotes are placed around the values.

The following list:

```
42
43
44
45
```

will be converted to:

```
( 42, 43, 44, 45 )
```

These two functions will only be available when text is selected which spans more than one line.

## 6.7. Programming related editor functions

The editor of the SQL Workbench/J offers two functions to aid in developing SQL statements which should be used inside your programming language (e.g. for SQL statements inside a Java program).

### 6.7.1. Copy Code Snippet

Suppose you have created the SQL statement that you wish to use inside your application to access your DBMS. The menu item SQL » Copy Code Snippet will create a piece of code that defines a String variable which contains the current SQL statement (or the currently selected statement if any text is selected).

If you have the following SQL statement in your editor:

```
SELECT p.name,
       p.firstname,
       a.street,
       a.zipcode,
       a.phone
FROM person p,
     address a
WHERE p.person_id = a.person_id;
```

When copying the code snippet, the following text will be placed into the clipboard

```
String sql="SELECT p.name, \n" +
"       p.firstname, \n" +
"       a.street, \n" +
"       a.zipcode, \n" +
"       a.phone \n" +
"FROM person p, \n" +
"     address a \n" +
"WHERE p.person_id = a.person_id; \n";
```

You can now paste this code into your application.

If you don't like the `\n` character in your code, you can disable the generation of the newline characters in your `workbench.settings` file. See [Manual settings](#) for details. You can also customize the [prefix](#) (`String sql =`) and the [concatenation character](#) that is used, in order to support the programming language that you use.

### 6.7.2. Clean Java code

When using the Copy Code Snippet feature during development, the SQL statement usually needs refinement after testing the Java class. You can Copy & Paste the generated Java code into SQL Workbench/J, then when you select the pasted text, and call SQL » Clean Java Code the selected text will be "cleaned" from the Java stuff around it. The algorithm behind that is as follows: remove everything up to the first `"` at the beginning of the line. Delete everything up to the first `"` searching backwards from the end of the line. Any trailing white-space including escaped characters such as `\n` will be removed as well. Lines starting with `//` will be converted to SQL single line comments starting with `--` (keeping existing quotes!). The following code:

```
String sql="SELECT p.name, \n" +
"      p.firstname, \n" +
"      a.street, \n" +
"      a.county, \n" +
"      a.zipcode, \n" +
"      a.phone \n" +
"FROM person p, \n" +
"      address a \n" +
"WHERE p.person_id = a.person_id; \n"
```

will be converted to:

```
SELECT p.name,
       p.firstname,
       a.street,
--"      a.county, " +
       a.zipcode,
       a.phone
FROM person p,
     address a
WHERE p.person_id = a.person_id;
```

### 6.7.3. Support for prepared statements

For better performance Java applications usually make use of [prepared statements](#). The SQL for a prepared statement does not contain the actual values that should be used e.g. in the WHERE clause, but uses quotation marks instead. Let's assume the above example should be enhanced to retrieve the person information for a specific ID. The code could look like this:

```
String sql="SELECT p.name, \n" +
"      p.firstname, \n" +
"      a.street, \n" +
"      a.zipcode, \n" +
"      a.phone \n" +
"FROM person p, \n" +
"      address a \n" +
"WHERE p.person_id = a.person_id; \n" +
"      AND p.person_id = ?";
```

You can copy and [clean](#) the SQL statement but you will not be able to execute it, because there is no value available for the parameter denoted by the question mark. To run this kind of statements, you need to enable the prepared statement detection using **SQL » Detect prepared statements**

Once the prepared statement detection is enabled, SQL Workbench/J will examine each statement to check whether it is a prepared statement. This examination is delegated to the JDBC driver and does cause some overhead when running the statement. For performance reasons you should disable the detection, if you are not using prepared statements in the editor (especially when running large scripts).

If a prepared statement is detected, you will be prompted to enter a value for each defined parameter. The dialog will list all parameters of the statement together with their type as returned by the JDBC driver. Once you have entered a value for each parameter, clicking OK will execute the statement using those values. When you execute the SQL statement the next time, the old values will be preselected, and you can either use them again or modify them before running the statement.

Once you are satisfied with your SQL statement, you can [copy](#) the statement and paste the Java code into your program.

Prepared statements are supported for SELECT, INSERT, UPDATE and DELETE statements.

This feature requires that the [getParameterCount\(\)](#) and [getParameterType\(\)](#) methods of the `ParameterMetaData` class are implemented by the JDBC driver and return the correct information about the available parameters.

The following drivers have been found to support (at least partially) this feature:

- [PostgreSQL](#), driver version 8.1-build 405
- [H2 Database Engine](#), Version 1.0.73
- [Apache Derby](#), Version 10.2
- [Firebird SQL](#), Jaybird 2.0 driver
- [HSQLDB](#), version 1.8.0

Drivers known to **not** support this feature:

- Oracle 10g driver (ojdbc14.jar)
- Microsoft SQL Server 2000/2005 driver (sqljdbc.jar)

## 7. Using SQL Workbench/J

### 7.1. Displaying help

You have two possibilities to display help for SQL Workbench/J. Either a HTML based help or a PDF version of the manual.

The HTML help is available through the menu item Help » Contents. It is expected that the HTML manual is stored in a directory called `manual` in the same directory where `sqlworkbench.jar` is located. This is automatically the case when you extract the distribution archive with sub-directories.

You can choose to display a single-page version of the HTML help (easier to search) or a multi-page version of the help that is easier to navigate. This can be switched in the options dialog, that is accessible from Tools » Option.

The PDF manual can be displayed by selecting Help » Manual. In order to be able to display the PDF manual, you need to define the path to the executable for the PDF reader in the [General options](#) section of the options dialog.

The file `SQLWorkbench-Manual.pdf` must be available in the directory where `sqlworkbench.jar` is located.

When connected to a database, the menu item Help » DBMS Manual will display the online manual for the current DBMS (if there is one). The default configuration includes the URLs for PostgreSQL, Oracle 10g, H2, HSQLDB, MySQL 5.1 and Microsoft SQL Server 2005.

The URL that is used to display the manual can be [changed](#) in the configuration file [workbench.settings](#).

### 7.2. Resizing windows

Every window that is opened by SQL Workbench/J for the first time is displayed with a default size. In certain cases it can happen that not all labels are readable or all controls are visible on the window. This can happen, e.g. when a large default font is selected (or defined through the look and feel).

Every window in SQL Workbench/J can be resized and will remember its size. So in case not everything is readable on a dialog, just resize the window so that the missing parts become visible, and that size will be kept for the future.

### 7.3. Executing SQL statements

#### 7.3.1. Control the statement to be executed

There are three different ways to execute a SQL command

##### Execute the selected text

When you press **Ctrl-E** or select SQL » Execute selected the currently selected text will be sent to the DBMS for execution. If no text is selected the complete contents of the editor will be sent to the database.

##### Execute current statement

When you press **Ctrl-Enter** or select SQL » Execute current the current statement will be executed. The "current" statement will be the text between the next delimiter before the current cursor position and the delimiter after the cursor position.

Example (| indicating the cursor position)

```
SELECT firstname, lastname FROM person;
```

```
DELETE FROM person| WHERE lastname = 'Dent';  
COMMIT;
```

When pressing Ctrl-Enter the DELETE statement will be executed

You can configure SQL Workbench/J to automatically jump to the next statement, after executing the current statement. Simply select SQL » Auto advance to next. The check mark next to the menu item indicates if this option is enabled. This option can also be changed through the [Options dialog](#)

### Execute All

If you want to execute the complete text in the editor regardless of the current selection, use the Execute all command. Either by pressing **Ctrl-Shift-E** or selecting SQL » Execute All

When executing all statements in the editor you have to delimit each statement, so that SQL Workbench/J can identify each statement. If your statements are not delimited using a semicolon, the whole editor text is sent as a single statement to the database. Some DBMS support this (e.g. Microsoft SQL Server), but most DBMS will throw an error in that case.

A script with two statements could look like this:

```
UPDATE person SET numheads = 2 WHERE name='Beeblebrox';  
COMMIT;
```

or:

```
DELETE FROM person;  
DELETE FROM address;  
COMMIT;
```

```
INSERT INTO person  
(id, firstname, lastname)  
VALUES  
(1, 'Arthur', 'Dent');
```

```
INSERT INTO person  
(id, firstname, lastname)  
VALUES  
(4, 'Mary', 'Moviestar');
```

```
INSERT INTO person  
(id, firstname, lastname)  
VALUES  
(2, 'Zaphod', 'Beeblebrox');
```

```
INSERT INTO person  
(id, firstname, lastname)  
VALUES  
(3, 'Tricia', 'McMillian');
```

```
COMMIT;
```

You can specify an [alternate delimiter](#) that can be used instead of the semicolon. See the description of the [alternate delimiter](#) for details. This is also needed when running DDL scripts (e.g. for stored procedures) that contain semicolons that should not delimit the statements.

As long as at least one statement is running the title of the main window will be prefixed with the » sign. Even if the main window is minimized you can still see if a statement is running by looking at the window title.

You can use variables in your SQL statements that are replaced when the statement is executed. Details on how to use variables can be found in the chapter Variable substitution.

JDBC drivers do not support multi-threaded execution of statements on the same physical connection. If you want to run two statements at the same time, you will need to enable the [Separate connection per tab](#) option in your connection profile. In this case SQL Workbench/J will open a physical connection for each SQL tab, so that statements in the different tabs can run concurrently.

## Statement history

When executing a statement the contents of the editor is put into an internal buffer together with the information about the text selection and the cursor position. Even when you select a part of the current text and execute that statement, the whole text is stored in the history buffer together with the selection information. When you select and execute different parts of the text and then move through the history you will see the selection change for each history entry.

The previous statement can be recalled by pressing **Alt-Left** or choosing **SQL » Previous Statement** from the menu. Once the previous statement(s) have been recalled the next statement can be shown using **Alt-Right** or choosing **SQL » Next Statement** from the menu. This is similar to browsing through the history of a web browser.

You can clear the statement history for the current tab, but selecting **SQL » Clear history**

When you clear the content of the editor (e.g. by selecting the whole text and then pressing the **Del** key) this will not clear the statement history. When you load the associated workspace the next time, the editor will automatically display the last statement from the history. You need to manually clear the statement history, if you want an empty editor the next time you load the workspace.

## 7.4. Displaying results

When you run SQL statements that produce a result (such as a **SELECT** statement) these results will be displayed in the lower pane of the window, next to the message panel. For each result that is returned from the server, one tab (labelled "Result") will be created. If you select and execute three **SELECT** statements, the lower pane will show three result tabs and the message tab. If your statement(s) did not produce any result, only the messages tab will be displayed.

SQL Workbench/J will read all rows returned by your statement into memory. When retrieving large results you might run out of memory. To adjust the memory available to SQL Workbench/J please refer to [this chapter](#).

When you run a SQL statement, the current results will be cleared and replaced by the new results. You can turn this off by selecting **SQL » Append new results**. Every result that is retrieved while this option is turned on, will be added to the set of result tabs, until you de-select this option. This can also be toggled using the button on the toolbar. Additional result tabs can be closed using **Data » Close result**

You can also run stored procedures that return result sets. These result will be displayed in the same way. For DBMS's that support multiple result sets from a single stored procedure (e.g. Microsoft SQL Server), one tab will be displayed for each result returned.

### 7.4.1. Displaying values with embedded newlines

Data from **VARCHAR** or **CHAR** columns is displayed as a single-line if the column's max. size is below 250 characters. If you have data in smaller columns that contains newlines (linebreaks) and you want to display directly in the result set, please adjust the limit to match your needs. The limit can be changed in the [Data Display Options](#).

### 7.4.2. Naming result tabs

You can change the name of the result tab associated with a statement. To give a result set a name you have to provide a comment before the SQL statement that contains the keyword **@wbresult** followed by a whitespace and then the name that should appear as the result's name. The keywords must be specified in lowercase!

The following examples executes two statements. The result for the first will be labelled "List of contacts" and the second will be labelled "List of companies":

```
-- @wbresult List of contacts
SELECT * FROM person;

/*
  @wbresult List of companies
  this will retrieve all companies from the database
*/
SELECT * FROM company;
```

As you can see, you can put the @wbresult keyword into a single-line or multi-line comment. The name that is used, will be everything after the keyword until the end of the line.

For the second select (with the multi-line comment), the name of the result tab will be List of companies, the comment on the second line will not be considered.

## 7.5. Creating stored procedures and triggers

SQL Workbench/J will send the contents of the editor unaltered to the DBMS, so executing DDL statements (CREATE TABLE, ...) is possible.

However when executing statements such as CREATE PROCEDURE which in turn contain valid SQL statement, delimited with a ; the SQL Workbench/J will send everything up to the first semicolon to the backend. In case of a CREATE PROCEDURE statement this will obviously result in an error as the statement is not complete.

This is an example of a CREATE PROCEDURE which will **not** work due to the embedded semicolon in the procedure source itself.

```
CREATE OR REPLACE FUNCTION proc_sample RETURN INTEGER
IS
  result INTEGER;
BEGIN
  SELECT max(col1) INTO result FROM sometable;
  RETURN result;
END;
```

When executing this script, Oracle would return an error because SQL Workbench/J will send everything up to the keyword INTEGER to the database. Obviously that fragment would not be correct.

The solution is to terminate the script with a character sequence called the "[alternate delimiter](#)". The value of this sequence can be configured in the [options dialog](#) as a global default, or per [connection profile](#) (so you can use different alternate delimiters for different database systems). The default is the forward slash / defined as a single line delimiter.

If a SQL statement is terminated with the alternate delimiter, that delimiter is used instead of a semicolon. This way the semicolons embedded in CREATE PROCEDURE statements will be sent correctly to the backend DBMS.

So the solution to the above problem is the following script:

```
CREATE OR REPLACE FUNCTION proc_sample RETURN INTEGER
IS
  result INTEGER;
BEGIN
  SELECT max(col1) INTO result FROM sometable;
  RETURN result;
```

```
END ;  
/
```

Note the trailing forward slash (/) at the end in order to "turn on" the use of the alternate delimiter. If you run scripts with embedded semicolons and you get an error, please verify the setting for your alternate delimiter.

### When is the alternate delimiter used?

As soon as the statement (or script) that you execute is terminated with the alternate delimiter, the alternate delimiter is used to separate the individual SQL statements. When you execute selected text from the editor, be sure to select the alternate delimiter as well, otherwise it will not be recognized (if the alternate delimiter is not selected, the statement to be executed does not end with the alternate delimiter).

You cannot mix the standard semicolon and the alternate delimiter inside one script.

If you use the alternate delimiter (by terminating the whole script with it), then **all** statements have to be delimited with it. You cannot mix the use of the normal semicolon and the alternate delimiter for one execution. The following statement (when executed completely) would produce an error message:

```
SELECT sysdate FROM DUAL;  
  
CREATE OR REPLACE FUNCTION proc_sample RETURN INTEGER  
IS  
    result INTEGER;  
BEGIN  
    SELECT max(coll) INTO result FROM sometable;  
    RETURN result;  
END;  
/
```

SQL Workbench/J will use the alternate delimiter present, the `SELECT` statement at the beginning will also be sent to the database together with the `CREATE` statement. This of course is an invalid statement. You will need to either select and run each statement individually or change the delimiter after the `SELECT` to the alternate delimiter.

## 7.6. Dealing with BLOB and CLOB columns

SQL Workbench/J supports reading and writing BLOB (Binary Large Object) or CLOB (Character Large Object) columns from and to external files. BLOB columns are sometimes also referred to as binary data. CLOB columns are sometimes also referred to as `LONG VARCHAR`. The exact data type depends on the DBMS used.

To insert and update LOB columns the usual `INSERT` and `UPDATE` statements can be used by using a special placeholder to define the source for the LOB data. When updating the LOB column, a different placeholder for BLOB and CLOB columns has to be used as the process of reading and sending the data is different for binary and character data.

When working with Oracle, only the 10g driver supports the standard JDBC calls used by SQL Workbench/J to read and write the LOB data. Earlier drivers will not work as described in this chapter.

### 7.6.1. Updating BLOB data through SQL

To update a BLOB (or binary) column, use the placeholder `{ $blobfile=path_to_file }` in the place where the actual value has to occur in the `INSERT` or `UPDATE` statement:

```
UPDATE theTable  
SET blob_col = { $blobfile=c:/data/image.bmp }
```

```
WHERE id=24;
```

SQL Workbench/J will rewrite the UPDATE statement and send the contents of the file located in `c:/data/image.bmp` to the database. The syntax for inserting BLOB data is similar. Note that some DBMS might not allow you to supply a value for the blob column during an insert. In this case you need to first insert the row without the blob column, then use an UPDATE to send the blob data. You should make sure to update only one row by specifying an appropriate WHERE clause.

```
INSERT INTO theTable
(id, blob_col)
VALUES
(42, {$blobfile=c:/data/image.bmp});
```

This will create a new record with `id=42` and the content of `c:/data/image.bmp` in the column `blob_col`

### 7.6.2. Updating CLOB data through SQL

The process of updating or inserting CLOB data is identical to the process for BLOB data. The only difference is in the syntax of the placeholder used to specify the source file. Firstly, the placeholder has to start with `{ $clobfile=` and can optionally contain a parameter to define the encoding of the source file.

```
UPDATE theTable
SET clob_col = { $clobfile=c:/data/manual.html encoding=utf8 }
WHERE id=42;
```

If you omit the encoding parameter, SQL Workbench/J will leave the data conversion to the JDBC driver (technically, it will use the `PreparedStatement.setAsciiStream()` method whereas with an encoding it will use the `PreparedStatement.setCharacterStream()` method).

The format of the `{ $clobfile= }` or `{ $blobfile= }` parameter has to be entered exactly as described here. You may not put e.g. spaces before or after the equal sign or the braces. If you do this, SQL Workbench/J will not recognize the parameter and will pass the statement "as is" to the JDBC driver.

### 7.6.3. Saving BLOB data to a file using SQL

To save the data stored in a BLOB column, the command [WbSelectBlob](#) can be used. The syntax of this command is similar to the regular SELECT command except that a target file has to be specified where the read data should be stored.

You can also use the [WbExport](#) command to export data. The contents of the BLOB columns will be saved into separate files. This works for both export formats (XML and Text).

### 7.6.4. BLOB data in the result set

When the result of your SELECT query contains BLOB columns, they will be displayed as ( BLOB ) together with a button. When you click on the button a dialog will be displayed allowing you to save the data to a file, view the data as text (using the selected encoding), display the blob as an image or display a hex view of the blob.

When displaying the BLOB content as a text, you can edit the text. When saving the data, the entered text will be converted to raw data using the selected encoding.

The window will also let you open the contents of the BLOB data with a predefined [external tool](#). The tools that are defined in the options dialog can be selected from a dropdown. To open the BLOB content with one of the tools, select the tool from the dropdown list, then click on the button Open with next to the external tools dropdown. SQL Workbench/J will then retrieve the BLOB data from the server, store it in a temporary file on your harddisk, and run the selected application, passing the temporary file as a parameter.

From within this information dialog, you can also upload a file to be stored in that BLOB column. The file contents will not be sent to the database server until you actually save the changes to your result set (this is the same for all changes you make directly in the result set, for details please refer to Editing the data)

When using the upload function in the BLOB info dialog, SQL Workbench/J will use the file content for any subsequent display of the binary data or the size information in the information dialog. You will need to retrieve the data, in order to use the blob data from the server.

## 7.7. Performance tuning when executing SQL

There are some configuration settings that affect the performance of SQL Workbench/J. On slow computers it is recommended to turn off the usage of the [animated icon](#) as the indicator for a running statement.

When running large scripts, the feedback which statement is executed can also slow down the execution. It is recommended to either turn off the feedback using [WBFEEDBACK OFF](#) or by [consolidating the script log](#)

When running [imports](#) or [exports](#) it is recommended to turn off the progress display in the statusbar that shows the current row that is imported/exported because this will slow down the process as well. In both cases you can use `-showProgress` to turn off the display (or set it to a high number such as 1000) in order to reduce the overhead caused by updating the screen.

## 7.8. SQL Macros

SQL Workbench/J offers so called SQL macros, or abbreviations. You can define macros for often used SQL statements. Once defined, you only need to enter the defined macro name and the underlying SQL statement will be executed.

### 7.8.1. Defining Macros

There are two ways to define a SQL macro.

If the current statement in the editor should be defined as a macro, select (highlight) the statement's text and select **Macros » Add SQL macro** from the main menu. You will be prompted to supply a name for the new macro. If you supply the name of an existing macro, the existing macro will be overwritten.

Alternatively you can add a new macro through **Macros » Manage Macros....** This dialog can also be used to delete and edit existing macros. You can put macros into separate groups (e.g. one for PostgreSQL macros, one for Oracle etc). If you have only one group defined (or only one visible group), all macros of that group will be listed in the menu directly. If you define more than one group, each group will appear as a separate sub-menu.

The order in which the macros (or groups) appear in the menu can be changed by dragging them to the desired position in the manage macro dialog.

### 7.8.2. Executing macros

To execute a macro, you can either type the alias you have defined, or select the macro from the **Macros** menu. Note that the alias needs to be unique to be used as a "SQL Statement". If you have two different macros in two different macro groups with the same name, it is not defined which of them will be executed.

To view the complete list of macros select **Macros » Manage Macros...** After selecting a macro, it can be executed by clicking on the **Run Run** button. If you check the option "Replace current SQL", then the text in the editor will be replaced with the text from the macro when you click on the run button.

Macros will not be evaluated when running in batch mode.

### 7.8.3. Parameters in macros

Apart from the SQL Workbench/J [script variables](#) for SQL Statements, additional "parameters" can be used inside a macro definition. These parameters will be replaced *before* replacing the script variables.

Parameter	Description
<code>\${selection}\$</code>	This parameter will be replaced with the currently selected text. The selected text will not be altered in any way.
<code>\${selected_statement}\$</code>	This behaves similar to <code>\${selection}\$</code> except that any trailing semicolon will be removed from the selection. Thus the macro definition can always contain the semicolon (e.g. when the macro actually defines a script with multiple statements) but when selecting the text, you do not need to worry whether a semicolon is selected or not (and would potentially break the script).
<code>\${current_statement}\$</code>	This key will be replaced with the current statement (without the trailing delimiter). The current statement is defined by the cursor location and is the statement that would be executed when using <a href="#">SQL » Execute current</a> [33]
<code>\${text}\$</code>	This key will be replaced with the complete text from the editor (regardless of any selection).

The SQL statement that is eventually executed will be logged into the message panel when invoking the macro from the menu. Macros that use the above parameters cannot correctly be executed by entering the macro alias in the SQL editor (and then executing the "statement").

The parameter keywords are case sensitive, i.e. the text `${SELECTION}$` will not be replaced!

This feature can be used to create SQL scripts that work only with an additional statement. e.g. for Oracle you could define a macro to run an explain plan for the current statement:

```
EXPLAIN PLAN FOR
${current_statement}$
;
```

```
COMMIT;
```

```
SELECT * FROM TABLE(DBMS_XPLAN.DISPLAY);
```

When you run this macro, it will run an `EXPLAIN PLAN` for the statement in which the cursor is currently located, and will immediately display the results for the explain. Note that the `${current_statement}$` keyword is terminated with a semicolon, as the replacement for `${current_statement}$` will never add the semicolon. If you use `${selection}$` instead, you have to pay attention to not select the semicolon in the editor before running this macro.

For PostgreSQL you can define a similar macro that will automatically run the `EXPLAIN` command for a statement:

```
explain ${current_statement}$
```

Another usage of the parameter replacement could be a SQL Statement that retrieves the rowcount that would be returned by the current statement:

```
SELECT count(*) FROM
(
    ${current_statement}$
)
```

## 7.9. Using workspaces

The complete history for all editor tabs is saved and loaded into one file, called a workspace. These workspaces can be saved and loaded to restore a specific editing context. You can assign a saved workspace to a [connection profile](#). When the connection is established, the workspace is loaded into SQL Workbench/J. Using this feature you can maintain a completely different set of statements for different connections.

If you do not assign a workspace to a connection profile, a workspace with the name `Default.wksp` will be used for storing the statement history. This default workspace is shared between **all** profiles that have no workspace assigned.

To save the current SQL statement history and the visible tabs into a new workspace, select **Workspace » Save Workspace as....**

The default file extension for workspaces is `wksp`.

Once you have loaded a workspace, you can save it with **Workspace » Save Workspace**. The current workspace is automatically saved, when you exit SQL Workbench/J.

An existing workspace can be loaded with **Workspace » Load Workspace**

If you have an external file open in one of the editor tabs, the filename itself will be stored in workspace. When loading the workspace SQL Workbench/J will try to load the external file again. If the file does not exist, the last history entry from the saved history for that tab will be displayed.

The workspace file itself is a normal ZIP file, which contains one file with the statement history for each tab. The individual files can be extracted from the workspace using your favorite UNZIP tool.

## 7.10. Saving and loading SQL scripts

The text from the current editor can be saved to an external file, by choosing **File » Save** or **File » Save as**. The filename for the current editor will be remembered. To close the current file, select **File » Discard file (Ctrl-F4)** or use the context menu on the tab label itself.

Detaching a file from the editor will remove the text from editor as well. If you only want to detach the filename from the editor but keep the text, then press **Ctrl-Shift-F4** or hold down the **Shift** key while selecting the Discard menu item.

When you load a SQL script and execute the statements, be aware that due to the history management in SQL Workbench/J the content of the external file will be placed into the history buffer. If you load large files, this might lead to massive memory consumption. Currently only the *number* of statements put into the history can be controlled, but not the total size of the history itself. You can prevent files from being put into the history by unchecking the option "Files in history" in the Editor section of the [options dialog](#).

## 7.11. Viewing server messages

### 7.11.1. PostgreSQL

PostgreSQL supports sending of messages to the client using the `RAISE` statement in PL/pgSQL. The following function will display a result set (with the number 42) and the message area will contain the message *Thinking hard...*

```
CREATE OR REPLACE FUNCTION the_answer()  
  RETURNS integer  
  LANGUAGE plpgsql
```

```
AS
$body$
BEGIN
    RAISE NOTICE 'Thinking hard...';
    RETURN 42;
END;
$body$
/
```

### 7.11.2. Oracle

For Oracle the DBMS\_OUTPUT package is supported. Support for this package can be turned on with the ENABLEOUT command. If this support is not turned on, the messages will not be displayed. This is the same as using the SET SERVEROUTPUT ON command in SQL\*Plus.

If you want to turn on support for DBMS\_OUTPUT automatically when connecting to an Oracle database, you can put the ENABLEOUT command into the [pre-connect](#) script.

Any message "printed" with DBMS\_OUTPUT.put\_line() will be displayed in the message part after the SQL command has finished. Please refer to the Oracle documentation if you want to learn more about the DBMS\_OUTPUT package.

```
dbms_output.put_line("The answer is 42");
```

Once the command has finished, the following will be displayed in the Messages tab.

```
The answer is 42
```

### 7.11.3. MS SQL Server

For MS SQL Server, any message written with the PRINT command will be displayed in the Messages tab after the SQL command has finished. The PRINT command is usually used in stored procedures for logging purposes, but it can also be used as a command on its own:

```
PRINT "Deleting records...";
DELETE from my_table WHERE value = 42;
PRINT "Done."
```

This will execute the DELETE. Once this script has finished, the Messages tab will contain the text:

```
Deleting records...
Done.
```

### 7.11.4. Other database systems

If your DBMS supports something similar, please let me know. I will try to implement it - provided I have free access to the DBMS. Please send your request to <[support@sql-workbench.net](mailto:support@sql-workbench.net)>.

## 7.12. Editing data

Once the data has been retrieved from the database, it can be edited directly in the result set. SQL Workbench/J assumes that enough columns have been retrieved from the table so that a unique identifier is available to identify the rows to be updated.

If you have primary keys defined for the underlying tables, those primary key columns will be used for the WHERE statements for UPDATE and DELETE. If no primary key columns are found, the JDBC driver is asked for a *best row identifier*. If that doesn't return any information, your defined [PK Mapping](#) will be queried. If still no PK columns can be found, you will be prompted to select the key columns based on the current result set.

The changes (modified, new or deleted rows) will not be saved to the database until you choose Data » Save Changes to Database.

If the update is successful (no database errors) a COMMIT will be sent to the database automatically.

If your SELECT was based on more than one table, you will be prompted to specify which table should be updated. Only columns for the chosen table will be included in the UPDATE or INSERT statements. If no primary key can be found for the update table, you will be prompted to select the columns that should be used to uniquely identify a row in the update table.

If an error is reported during the update, a ROLLBACK will be sent to the database. The COMMIT or ROLLBACK will only be sent if [autocommit](#) is turned off.

Columns containing BLOB data will be displayed with a ... button. By clicking on that button, you can view the blob data, save it to a file or upload the content of a file to the DBMS. Please refer to BLOB support for details.

When editing, SQL Workbench/J will highlight columns that are defined as NOT NULL in the database. You can turn this feature off, or change the color that is used in the [options dialog](#).

When editing date, timestamp or time fields, the format specified in the [options dialog](#) is used for parsing the entered value and converting that into the internal representation of a date. The value entered must match the format defined there.

If you want to input the current date and time you can use `now`, `today`, `sysdate`, `current_timestamp`, `current_date` instead. This will then use the current date & time and will convert this to the appropriate data type for that column. e.g. `now` will be converted to the current time for a time column, the current date for a date column and the current date/time for a timestamp column. These keywords also work when importing text files using [WbImport](#) or importing a text file into the result set. The exact keywords that are recognized can be configured in the [settings file](#).

If the option [Empty String is NULL](#) is disabled for the current connection profile, you can still set a column's value to null when editing it. To do this, double click the current value, so that you can edit it. In the context menu (right mouse button) the option "Set to NULL" is available. This will clear the value and set it to NULL. You can assign a shortcut to this action, but the shortcut will only be active when editing a value inside a column.

## 7.13. Deleting rows from the result

To delete a row from the result, select Data » Delete Row from the menu. This will remove the currently selected row(s) from the result and will mark them for deletion once the changes are saved. No foreign key checks will be done when using this option.

The generated DELETE statements will fail if the deleted row(s) are still referenced by another table. In that case, you can use Delete With Dependencies.

## 7.14. Deleting rows with foreign keys

To delete rows including all dependent rows, choose Data » Delete With Dependencies. In this case SQL Workbench/J will analyze all foreign keys referencing the update table, and will generate the necessary DELETE statements to delete the dependent rows, before sending the DELETE for the selected row(s).

Delete With Dependencies might take some time to detect all foreign key dependencies for the current update table. During this time a message will be displayed in the status bar. The selected row(s) will not be removed from the result set until the dependency check has finished.

Note that the generated SQL statements to delete the dependent rows will only be shown if you have enabled the preview of generated DML statements in the [options dialog](#)

You can also generate a script to delete the selected and all depending rows through Data » Generate delete script. This will not remove any rows from the current result set, but instead create and display a script that you can run at a later time.

## 7.15. Navigating referenced rows

Once you have retrieved data from a table that has foreign key relations to other tables, you can navigate the relationship for specific rows in the result set. Select the rows for which you want to find the data in the related tables, then right click inside the result set. In the context menu two items are available:

Referenced rows  
Referencing rows

Consider the following tables:

Referenced rows  
Referencing rows  
BASE (b\_id, name)  
DETAIL (d\_id, base\_id, description) with base\_id referencing BASE(b\_id)  
MORE\_DETAIL (md\_id, detail\_id, description) with detail\_id referencing DETAIL (d\_id)

The context menu for the selected rows will give you the choice in which SQL tab you want the generated `SELECT` to be pasted. This is similar to the [Put SELECT into](#) feature in the table list of the DbExplorer.

Once you have obtained a result set from the table BASE, select (mark) the rows for which you want to retrieve the related rows, e.g. the one where id=1. Using Referencing rows » DETAIL SQL Workbench/J will create the following statement:

```
SELECT *  
FROM DETAIL  
WHERE base_id = 1;
```

The result of the generated statement will always be added to the existing results of the chosen SQL panel. By default the generated SQL statement will be appended to the text editor. If you don't want the generated statement to be appended to the editor, hold down the `Ctrl` key while selecting the desired menu item. In that case, the generated statement will only be written to the messages panel of the SQL tab. If the target tab contains an external file, the statement will never be appended to the editor's text.

To navigate from the child data to the "parent" data, use Referenced rows

The additional result tabs can be closed using Data » Close result

## 7.16. Sorting the result

The result will be displayed in the order returned by the DBMS (i.e. if you use an `ORDER BY` in your `SELECT` the display will be displayed as sorted by the DBMS).

You can change the sorting of the displayed data by clicking on the header of the column that should be used for sorting. After the first click the data will be sorted ascending (lower values at the top). If you click on the column again the sort order will be reversed. The sort order will be indicated by a little triangle in the column header. If the triangle points upward the data is sorted ascending, if it points downward the data is sorted descending. Clicking on a column will remove any previous sorting (including the secondary columns) and apply the new sorting.

If you want to sort by more than one column, hold down the **Ctrl** key while clicking on the (second) header. The initial sort order is ascending for that additional column. To switch the sort order hold down the **Ctrl** key and click on the column header again. The sort order for all "secondary" sort columns will be indicated with a slightly smaller triangle than the one for the primary sort column.

To define a different secondary sort column, you first have to remove the current secondary column. This can be done by holding down the **Shift** key and clicking on the secondary column again. Note that the data will not be resorted. Once you have removed the secondary column, you can define a different secondary sort column.

By default SQL Workbench/J will use "ASCII" sorting which is case-sensitive and will not sort special characters according to your language. You can change the locale that is used for sorting data in the [options dialog](#) under the category "Data Display". Sorting using a locale is a bit slower than "ASCII" sorting.

## 7.17. Filtering the result

Once the data has been retrieved from the Server it can be filtered with the need to re-retrieve the data. You can define the filter in two ways: either enter column and their filter values manually, or create a filter from the currently selected values in the result set.

### 7.17.1. Defining a filter manually

To define a filter, click on the **Filter** button () in the toolbar or select Data » Filter data. A dialog will appear where you can define a filter for the current result set. Each line in the filter dialog defines an expression that will be applied to the column selected in the first dropdown. If you select \* for the column, the filter condition will be applied to all columns of the result set.

To add a multi-column expression, press the **More** button, to create a new line. To remove a column expression

from the filter, click the **Remove** () button. For character based column data, you can select to ignore the case of the column's data when applying the expression, i.e. when **Ignore case** is selected, the expression 'NAME = arthur' will match the column value 'Arthur', and 'ARTHUR'.

By default, the column expressions are combined with an **OR**, i.e. that a row will be displayed if at least one of the column expressions evaluates to true. If you want to view only rows where **all** column expressions must match, select the **AND** radio button at the top of the dialog.

Once you have saved a filter to an external file, this filter will be available in the pick list, next to the filter icon. The list will show the last filters that were saved. The number of items displayed in this drop down can be controlled in the [settings file](#).

### 7.17.2. Defining a filter from the selection

You can also quickly filter the data based on the value(s) of the currently selected column(s). To apply the filter, select the column values by which you want to filter then click on the **Quickfilter** button () in the toolbar or select Data » Filter by value from the menu bar.

Using the **Alt** key you can select individual columns of one or more rows. Together with the **Ctrl** key you can select e.g. the first, third and fourth column. You can also select the e.g. second column of the first, second and fifth row.

Whether the quick filter is available depends on the selected rows and columns. It will be enabled when:

- You have selected one or more columns in a single row

- You have selected one column in multiple rows

If only a single row is selected, the quick filter will use the values of the selected columns combined with AND to define the filter (e.g. username = 'Bob' AND job = 'Clerk'). Which columns are used depends on the way you select the row and columns. If the whole row in the result is selected, the quick filter will use the value of the focused column (the one with the yellow rectangle), otherwise the individually selected columns will be used.

If you select a single column in multiple rows, this will create a filter for that column, but with the values will be combined with OR (e.g. name = 'Dent' OR name = 'Prefect'). The quick filter will not be available if you select more than one column in multiple rows.

Once you have applied a quick filter, you can use the regular filter definition dialog to check the definition of the filter or to further modify it.

## 7.18. Running stored procedures

Stored procedures can be executed by using the SQL Workbench/J command `WbCall` which replaces the standard commands available for the DBMS (e.g. `CALL` or `EXECUTE`). By using a special command, additional checks can be carried out by SQL Workbench/J. This is especially necessary when dealing with OUT parameters or REF CURSORS.

The simplest way to run a stored procedure is:

```
WbCall my_proc( );
```

When using Microsoft SQL Server, `WbCall` is not necessary as long as the stored procedure does not have OUT or REF CURSOR parameters. So with SQL Server you can simply write:

```
sp_who2 ;
```

To run the stored procedure `sp_who2` and to display its results.

For more details on running a stored procedure with OUT parameters or REF CURSORS please refer to the description of the [WbCall](#) command.

## 7.19. Export result data

You can export the data of the into local files of the following formats:

- HTML
- SQL statements (INSERT, UPDATE or DELETE & INSERT)
- XML format
- Tab separated text file. Columns are separated with a tab, rows are separated with a newline character
- Spreadsheet Format (OpenDocument, Microsoft Excel)

In order to write the proprietary Microsoft Excel format, additional libraries are needed. Please refer to [Exporting Excel files](#) for details.

To save the data from the current result set into an external file, choose Data » Save Data as You will be prompted for the filename. On the right side of the file dialog you will have the possibility to define the type of the export. The export parameters on the right side of the dialog are split into two parts. The upper part defines parameters that are available for all export types. These are the encoding for the file, the format for date and date/time data and the columns that should be exported.

All format specific options that are available in the lower part, are also available when using the [WbExport](#) command. For a detailed discussion of the individual options please refer to that section.

The options `SQL UPDATE` and `SQL DELETE/INSERT` are only available when the current result has a single table that can be updated, and the primary key columns for that table could be retrieved. If the current result does not have key columns defined, you can select the key columns that should be used when creating the file. If the current result is retrieved from multiple tables, you have to supply a table name to be used for the SQL statements.

Please keep in mind that exporting the data from the result set requires you to load everything into memory. If you need to export data sets which are too big to fit into memory, you should use the [WbExport](#) command to either create SQL scripts or to save the data as text or XML files that can be imported into the database using the [WbImport](#) command. You can also use `SQL » Export query result` to export the result of the currently selected SQL statement.

## 7.20. Copy data to the clipboard

You can also copy the data from the result into the system in four different formats. In any case default settings are used for the various options of the respective format.

- Text (tab separated)

This will use a tab as the column separator, and will not quote any values. The end-of-line sequence will be a newline (Unix style) and the column headers will be part of the copied data. Special characters (e.g. newlines) in the actual data will not be replaced (as it is possible with the [WbExport](#) command).

When you hold down the **Shift** key when you select the menu item, the column headers will not be copied to the clipboard. When you hold down the **Ctrl** key when selecting the menu item, you can choose which columns should be copied to the clipboard. Pressing **Shift** and **Ctrl** together is also supported.

- SQL (INSERT, UPDATE, or DELETE & INSERT)

The end-of-line sequence will be a newline (Unix style). No cleanup of data will be done as it is possible with the [WbExport](#) command, apart from correctly quoting single quotes inside the values (which is required to generate valid SQL)

As with the `Save Data as` command, the options `SQL UPDATE` and `SQL DELETE/INSERT` are only available when the current result set is updateable. If no key columns could be retrieved for the current result, you can manually define the key columns to be used, using `Data » Define key columns`

If you do not want to copy all columns to the clipboard, hold down the **CTRL** key while selecting one of the menu items related to the clipboard. A dialog will then let you select the columns that you want to copy.

Alternatively you can hold down the **Alt** key while selecting rows/columns in the result set. This will allow you to select only the columns and rows that you want to copy. If you then use one of the formats available in the `Copy` selected submenu, only the selected cells will be copied. If you choose to copy the data as `UPDATE` or `DELETE/INSERT` statements, the generated SQL statements will not be correct if you did not select the primary key of the underlying update table.

## 7.21. Import data into the result set

### 7.21.1. Import a file into the current result set

SQL Workbench/J can import tab separated text files into the current result set. This means, that you need to issue the appropriate `SELECT` statement first. The structure of the file has to match the structure of the result set, otherwise an error will occur. To initiate the import select `Data » Import file`

When selecting the file, you can change some parameters for the import:

Option	Description
Header	if this option this is checked, the first line of the import file will be ignored
Delimiter	the delimiter used to separate column values. Enter \t for the tab character
Date Format	The <a href="#">format</a> in which date fields are specified.
Decimal char	The character that is used to indicate the decimals in numeric values (typically a dot or a comma)
Quote char	The character used to quote values with special characters. Make sure that each opening quote is followed by a closing quote in your text file.

You can also import text and XML files using the [WbImport](#) command. Using the `WbImport` command is the recommended way to import data, as it is much more flexible, and - more important - it does not read the data into memory.

### 7.21.2. Import the clipboard into the current result

You can import the contents of the into the current result, if the format matches the result set. When you select Data » Import from Clipboar SQL Workbench/J will check if the current clipboard contents can be imported into the current result. The data can automatically be imported if the first row of the data contains the column names. One of the following two conditions must be true in order for the import to succeed

- The columns are delimited with a tab character and the first row contains column names. All matching columns will then be imported
- If no column name matches (i.e. no header row is present) but the number of columns (identified by the number of tab characters in the first row) is identical to the number of columns in the current result.

If SQL Workbench/J cannot identify the format of the clipboard a dialog will be opened where you can specify the format of the clipboard contents. This is mainly necessary if the delimiter is not the tab character. You can manually open that dialog, by holding down the **Ctrl** key when clicking on the menu item.

## 8. Variable substitution in SQL statements

### 8.1. Defining variables

You can define variables within SQL Workbench/J that can be referenced in your SQL statements. This is done through the internal command `WbVarDef`, e.g.: `wbvardef myvar=42`. This example defines a variable with the name `myvar` and the value `42`. If the variable does not exist, it will be created. If it exists its value will be overwritten with the new value. To remove a variable simply set its value to nothing: `wbvardef myvar=`. Alternatively you can use the command `wbvardelete myvar` to remove a variable definition.

Variable substitution is also done within [Macros](#). If your macro definition contains a reference to a SQL Workbench/J variable, this will be treated the same way as in regular statements.

Variables are case sensitive.

Variables can also be read from a properties file, either by specifying `-file=filename` for the `WbVarDef` command, or by passing the `-vardef` parameter when starting SQL Workbench/J. Please see the description for the [command line parameters](#) for details.

```
wbvardef -file=/temp/myvars.def
```

This file has to be a standard Java "properties" file. Each variable is listed on a single line in the format `variable=value`. Lines starting with a `#` character are ignored (comments). Assuming the file `myvars.def` had the following content:

```
#Define the ID that we need later
var_id=42
person_name=Dent
another_variable=24
```

After executing `wbvardef -file=/temp/myvars.def` there would be three variables available in the system: `var_id`, `person_name`, `another_variable`, that could be used e.g. in a `SELECT` query:

```
SELECT * FROM person where name='${person_name}' or id=${var_id};
```

SQL Workbench/J would expand the variables and send the following statement to the server:

```
SELECT * FROM person where name='Dent' or id=42;
```

A variable can also be defined as the result of a `SELECT` statement. This is indicated by using `@` as the first character after the equal sign. The `SELECT` needs to be enclosed in double quotes, if you are using single quotes e.g. in the `where` clause:

```
wbvardef myvar=@"SELECT id FROM person WHERE name='Dent' "
```

When executing the statement, SQL Workbench/J uses the first column of the first row of the result set for retrieving the value for the variable. Everything else (additional columns, additional rows) will be ignored.

You can also use `PreparedStatements` in the SQL editor. In this case the parameters are denoted by quotation marks and you will be prompted for a value each time you run the statement (which is different to using SQL Workbench/J variables. For details on how to use prepared statements refer to [support for prepared statements](#)

## 8.2. Editing variables

To view a list of currently defined variables execute the command `WBVARLIST`. This will display a list of currently defined variables and their values. You can edit the resulting list similar to editing the result of a `SELECT` statement. You can add new variables by adding a row to the result, remove existing variables by deleting rows from the result, or edit the value of a variable. If you change the name of a variable, this is the same as removing the old, and creating a new one.

## 8.3. Using variables in SQL statements

The defined variables can be used by enclosing them in special characters inside the SQL statement. The default is set to `[$]` and `]` thus you can use a variable this way:

```
SELECT firstname, lastname FROM person WHERE id=[$id_variable];
```

If you have a variable with the name `id_variable` defined, the sequence `[$id_variable]` will be replaced with the current value of the variable.

Variables will be replaced *after* replacing macro [parameters](#).

If the SQL statement requires quotes for the SQL literal, you can either put the quotes into the value of the variable (e.g. `wbvardef name=" 'Arthur' "`) or you put the quotes around the variable's placeholder, e.g.: `WHERE name= '[$name] ' ;`

As you can see the variable substitution is also done inside quoted literals.

If you are using values in your regular statements that actually need the prefix (`[$]` or suffix (`]`) characters, please make sure that you have no variables defined. Otherwise you will unpredictable results. If you want to use variables but need to use the default prefix for marking variables in your statements, you can configure a different prefix and suffix for flagging variables. To change the the prefix e.g. to `%#` and the suffix (i.e end of the variable name) to `#`, add the following lines to your `workbench.settings` file:

```
workbench.sql.parameter.prefix=%#  
workbench.sql.parameter.suffix=#
```

You may leave the suffix empty, but the prefix definition may not be empty.

## 8.4. Prompting for values during execution

You can also use variables in a way that SQL Workbench/J will prompt you during execution of a SQL statement that contains a variable.

If you want to be prompted for a value, simply reference the value with a quotation mark in front of its name:

```
SELECT id FROM person WHERE name like '[$?search_name]%'
```

If you execute this statement, SQL Workbench/J will prompt you for the value of the variable `search_name`. If the variable is already defined you will see the current value of the variable. If the variable is not yet defined it will be implicitly defined with an empty value.

If you use a variable more then once in your statement it is sufficient to define it once as a prompt variable. Prompting for a variable value is especially useful inside a macro definition.

You can also define a conditional prompt with using an ampersand instead of a quotation mark. In this case you will only be prompted if no value is assigned for the variable:

```
SELECT id FROM person WHERE name like '${&search_name}%'
```

The first time you execute this statement (and no value has been assigned to `search_name` before using `WBVARDEF` or on the commandline) you will be prompted for a value for `search_name`. Any subsequent execution of the statement (or any other statement referencing `${&search_name}`) will re-use the value you entered.

## 9. Using SQL Workbench/J in batch files

SQL Workbench/J can also be used from batch files to execute SQL scripts. This can be used to e.g. automatically extract data from a database or run other SQL queries or statements.

To start SQL Workbench/J in batch mode, either the `-script` or `-command` must be passed as an argument on the commandline.

If neither of these parameters is present, SQL Workbench/J will run in GUI mode.

When running SQL Workbench/J on Windows, you either need to use `sqlwbconsole` or start SQL Workbench/J using the Java command. You **cannot** use the [Windows launcher](#) `SQLWorkbench.exe`, as it will run in the background without a console window, and thus you will not see any output from the batch run.

Please refer to [Starting SQL Workbench/J](#) for details on how to start SQL Workbench/J with the `java` command.

When you need to quote parameters inside batch or shell scripts, you have to use single quotes (`'test-script.sql'`) to quote these values. Most command line shells (including Windows®) do not pass double quotes to the application and thus the parameters would not be evaluated correctly by SQL Workbench/J

If you want to start the application from within another program (e.g. an [Ant](#) script or your own program), you will need to start SQL Workbench/J's main class directly.

```
java -cp sqlworkbench.jar workbench.WbStarter
```

Inside an Ant build script this would need to be done like this:

```
<java classname="workbench.WbStarter" classpath="sqlworkbench.jar" fork="true">
  <arg value="-profile='my profile'"/>
  <arg value="-script=load_data.sql"/>
</java>
```

The parameters to specify the connection and the SQL script to be executed have to be passed on the commandline.

### 9.1. Specifying the connection

When running SQL Workbench/J in batch mode, you can define the connection using a [profile name](#) or specifying the connection properties [directly](#).

### 9.2. Specifying the script file(s)

The script that should be run is specified with the parameter `-script=<filename>`. Multiple scripts can be specified by separating them with a comma. The scripts will then be executed in the order in which they appear in the commandline. If the filenames contain spaces or dashes (i.e. `test-1.sql`) the names have to be quoted.

You can also execute several scripts by using the [WbInclude](#) command inside a script.

### 9.3. Specifying a SQL command directly

If you do not want to create an extra SQL script just to run one or more short SQL commands, you can specify the commands to be executed directly with the `-command` parameter. To specify more than one SQL statement use the standard delimiter to delimit them, e.g. `-command='delete from person; commit;'`

If a script has been specified using the `-script` parameter, the `-command` parameter is ignored.

## 9.4. Specifying a delimiter

If your script files use a non-standard delimiter for the statements, you can specify an alternate delimiter through the profile or through the `-altDelimiter` parameter. The alternate delimiter should be used if you have several scripts that use the regular semicolon and the alternate delimiter. If your scripts exceed a certain size, they won't be processed in memory and detecting the alternate delimiter does not work in that case. If this is the case you can use the `-delimiter` switch to change the default delimiter for all scripts. The usage of the alternate delimiter will be disabled if this parameter is specified.

## 9.5. Specifying an encoding for the file(s)

In case your script files are not using the default encoding, you can specify the encoding of your script files with the `-encoding` parameter. Note that this will set for all script files passed on the commandline. If you need to run several scriptfiles with different encodings, you have to create one "master" file, which calls the individual files using the [WbInclude](#) command together with its `-encoding` parameter.

## 9.6. Specifying a logfile

If you don't want to write the messages to the default logfile which is defined in `workbench.settings` an alternate logfile can be specified with `-logfile`

## 9.7. Handling errors

To control the behavior when errors occur during script execution, you can use the parameter `-abortOnError=[true|false]`. If any error occurs, and `-abortOnError` is `true`, script processing is completely stopped (i.e. SQL Workbench/J will be stopped). The only script which will be executed after that point is the script specified with the parameter `-cleanupError`.

If `-abortOnError` is `false` all statements in all scripts are executed regardless of any errors. As no error information is evaluated the script specified in `-cleanupSuccess` will be executed at the end.

If this parameter is not supplied it defaults to `true`, meaning that the script will be aborted when an error occurs.

You can also specify whether errors from DROP commands should be ignored. To enable this, pass the parameter `-ignoreDropErrors=true` on the commandline. This works when connecting through a profile or through a full connection specification. If this parameter is set to `true` only a warning will be issued, but any error reported from the DBMS when executing a DROP command will be ignored.

Note that this will not always have the desired effect. When using e.g. PostgreSQL with autocommit off, the current transaction will be aborted by PostgreSQL until a COMMIT or ROLLBACK is issued. So even if the error during the DROP is ignored, subsequent statements will fail nevertheless.

## 9.8. Specify a script to be executed on successful completion

The script specified with the parameter `-cleanupSuccess=<filename>` is executed as the last script if either no error occurred or `AbortOnError` is set to `false`.

If you update data in the database, this script usually contains a COMMIT command to make all changes permanent. The abort script usually contains a ROLLBACK command.

## 9.9. Specify a script to be executed after an error

The script specified with the parameter `-cleanupError=<filename>` is executed as the last script if `AbortOnError` is set to true and an error occurred during script execution.

The failure script usually contains a ROLLBACK command to undo any changes to the database in case an error occurred.

## 9.10. Ignoring errors from DROP statements

When connecting [without a profile](#), you can use the switch `-ignoreDropErrors=[true|false]` to ignore errors that are reported from DROP statements. This has the same effect as connecting with a profile where the [Ignore DROP errors](#) property is enabled.

## 9.11. Changing the connection

You can change the current connection inside a script using the command [WbConnect](#).

## 9.12. Controlling console output during batch execution

Any output generated by SQL Workbench/J during batch execution is sent to the standard output (stdout, System.out) and can be redirected if desired.

### 9.12.1. Displaying result sets

If you are running SELECT statements in your script without "consuming" the data through an [WbExport](#), you can optionally display the results to the console using the parameter `-displayResult=true`. If this parameter is not passed or set to false, results sets will not be visible (for a SELECT statement you will simply see the message 'SELECT executed successfully').

### 9.12.2. Controlling execution feedback

When running statements, SQL Workbench/J reports success or failure of each statement. Inside a SQL script the [WbFeedback](#) command can be used to control this feedback. If you don't want to add a `WbFeedback` command to your scripts, you can control the feedback using the `-feedback` switch on the command line. Passing `-feedback=false` has the same effect as putting a `WbFeedback off` in your script.

As displaying the feedback can be quite some overhead especially when executing thousands of statements in a script file, it is recommended to turn off the result logging using `WbFeedback off` or `-feedback=false`

To only log a summary of the script execution (per script file), specify the parameter `-consolidateMessages=true`. This will then display the number of statements executed, the number of failed statements and the total number of rows affected (updated, deleted or inserted).

When using `-feedback=false`, informational messages like the total number of statements executed, or a successful connection are not logged either.

### 9.12.3. Controlling statement progress information

Several commands (like `WbExport`) show progress information in the statusbar. When running in batch mode, this information is usually not shown. When you specify `-showProgress=true` these messages will also be displayed on the console.

### 9.13. Running batch scripts interactively

By default neither parameter prompts nor execution confirmations ("[Confirm Updates](#)") are processed when running in batch mode. If you have batch scripts that contain [parameter prompts](#) and you want to enter values for the parameters while running the batch file, you have to start SQL Workbench/J using the parameter `-interactive=true`.

### 9.14. Setting configuration properties

When running SQL Workbench/J in batch mode, with no `workbench.settings` file, you can set any property by passing the property as a system property when starting the JVM. To change the loglevel to `DEBUG` you need to pass `-Dworkbench.log.level=DEBUG` when starting the application:

```
java -Dworkbench.log.level=DEBUG -jar sqlworkbench.jar
```

### 9.15. Examples

For readability the examples in this section are displayed on several lines. If you enter them manually on the commandline you will need to put everything in one line, or use the escape character for your operating system to extend a single command over more than one input line.

#### Connect to the database without specifying a connection profile:

```
java -jar sqlworkbench.jar -url=jdbc:postgresql:/dbserver/mydb
    -driver=org.postgresql.Driver
    -username=zaphod
    -password=vogsphere
    -driverjar=C:/Programme/pgsql/pg73jdbc3.jar
    -script='test-script.sql'
```

This will start SQL Workbench/J, connect to the database server as specified in the connection parameters and execute the script `test-script.sql`. As the script's filename contains a dash, it has to be quoted. This is also necessary when the filename contains spaces.

#### Executing several scripts with a cleanup and failure script:

```
java -jar sqlworkbench.jar
    -script='c:/scripts/script-1.sql','c:/scripts/script-2.sql',c:/scripts/script3.sql
    -profile=PostgreSQL
    -abortOnError=false
    -cleanupSuccess=commit.sql
    -cleanupError=rollback.sql
```

Note that you need to quote each file individually (where it's needed) and not the value for the `-script` parameter

#### Run a SQL command in batch mode without using a script file

The following example exports the table "person" without using the `-script` parameter:

```
java -jar sqlworkbench.jar  
-profile='TestData'  
-command='WbExport -file=person.txt -type=text -sourceTable=person'
```

The following example shows how to run two different SQL statements without using the -script parameter:

```
java -jar sqlworkbench.jar  
-profile='TestData'  
-command='delete from person; commit;'
```

## 10. Using SQL Workbench/J in console mode

SQL Workbench/J can also be used from the commandline without starting the GUI, e.g. when you only have a console window (Putty, SSH) to access the database. In that case you can either run scripts using the [batch mode](#), or start SQL Workbench/J in console mode, where you can run statements interactively, similar to the GUI mode (but of course with less comfortable editing possibilities).

When using SQL Workbench/J in console mode, you **cannot** use the [Windows launcher](#). Please use the supplied scripts `sqlwbconsole.cmd` (Windows batch file) or `sqlwbconsole.sh` (Unix shell script) to start the console. On Windows you can also use the `sqlwbconsole.exe` program to start the console mode.

When starting SQL Workbench/J in console mode, you can define the connection using a [profile name](#) or specifying the connection properties [directly](#). Additionally you can specify all parameters that can be used in [batch mode](#).

The following batch mode parameters will be ignored in console mode:

`script` - you cannot specify a script to be run during startup. If you want to run a script in console mode, use the command [WbInclude](#).  
`encoding` - as you cannot specify a script, the encoding parameter is ignored as well  
`displayResult` - always true in console mode  
`cleanupSuccess` and `cleanupError` - as no script is run, there is no "end of script" after which a "cleanup" is necessary  
`abortOnError`

### 10.1. Entering statements

After starting the console mode, SQL Workbench/J displays the prompt `SQL>` where you can enter SQL statements. The statement will not be sent to the database until it is either terminated with the standard semicolon, or with the alternate delimiter (that can be specified either in the used connection profile or on the commandline when starting the console mode).

As long as a statement is not complete, the prompt will change to `. . >`. Once a delimiter is identified the statement(s) are sent to the database.

```
SQL> SELECT *<ENTER>  
..>FROM person;
```

A delimiter is only recognized at the end of the input line, thus you can enter more than one statement on a line (or multiple lines) if the intermediate delimiter is not at the end of one of the input lines:

```
SQL> DELETE FROM person; rollback;  
DELETE executed successfully  
4 row(s) affected.  
  
ROLLBACK executed successfully  
SQL>
```

### 10.2. Exiting console mode

To exit the application in console mode, enter `exit` when the default prompt is displayed. If the "continuation prompt" (`. . >`) is displayed, this will not terminate the application. The keyword `exit` may not be terminated with a semicolon.

### 10.3. Setting or changing the connection

If you did not specify a connection on the commandline when starting the console, you can set or change the current connection in console mode using the [WbConnect](#) command. Using `WbConnect` in console mode will automatically close the current connection, before establishing the new connection.

To disconnect the current connection in console mode, run the statement `WbDisconnect`. Note that this statement is only available in console mode.

### 10.4. Displaying result sets

If you are running `SELECT` statements in console mode, the result is displayed on the screen in "tabular" format. Note that SQL Workbench/J reads the whole result into memory in order to be to adjust the column widths to the displayed data.

You can disable the buffering of the results using the commandline parameter `bufferResults=false`. In that case, the width of the displayed columns will not be adjusted properly. The column widths are taken from the information returned by the driver which typically results in a much larger display than needed.

The output in tabular format (if results are buffered) looks like this:

```
SQL> select id, firstname, lastname, comment from person;
id | firstname | lastname | comment
---+-----+-----+-----
1  | Arthur   | Dent    | this is a comment
2  | Zaphod   | Beeblebrox |
4  | Mary     | Moviestar | comment
3  | Tricia   | McMillian | test1

(4 Rows)
SQL>
```

If the size of the column values exceed the console's width the display will be wrapped, which makes it hard to read. In that case, you can switch the output so that each column is printed on a single line.

This is done by running the statement: `WbDisplay record`

```
SQL> WbDisplay record;
Display changed to single record format
Execution time: 0.0s
SQL> select id, firstname, lastname, comment from person;
---- [Row 1] -----
id      : 1
firstname : Arthur
lastname  : Dent
comment   : this is a very long comment that would not fit onto the screen when printed as
---- [Row 2] -----
id      : 2
firstname : Zaphod
lastname  : Beeblebrox
comment   :
---- [Row 3] -----
id      : 4
firstname : Mary
lastname  : Moviestar
comment   :
```

```
---- [Row 4] -----
id      : 3
firstname : Tricia
lastname : McMillian
comment  :

(4 Rows)
SQL>
```

To switch back to the "tabular" display, use: `WbDisplay tab`.

## 10.5. Running SQL scripts that produce a result

Normally when executing a SQL script using [WbInclude](#), the result of such a script (e.g. when it contains a `SELECT` statement) is not displayed on the console.

To run such a script, use the command `WbRun` instead of `WbInclude`. If you have the following SQL script (named `select_person.sql`):

```
SELECT *
FROM person;
```

and execute that using the `WbInclude` command:

```
SQL> WbInclude -file=select_person.sql;
SQL> Execution time: 0.063s
```

If you execute this script using `WbRun` the result of the script is displayed:

```
SQL> WbRun select_people.sql;
select *
from person;
```

id	firstname	lastname
1	Arthur	Dent
4	Mary	Moviestar
2	Zaphod	Beeblebrox
3	Tricia	McMillian

```
(4 Rows)
Execution time: 0.078s
SQL>
```

## 10.6. Controlling the number of rows displayed

In the SQL Workbench/J GUI window, you can limit the result of a query by entering a value in the "Max. Rows" field. If you want to limit the number of rows in console mode you can do this by running the statement

```
SQL> set maxrows 42;
MAXROWS set to 42
Execution time: 0.0s
SQL>
```

This will limit the number of rows retrieved to 42.

SET MAXROWS has no effect when run as a [post-connect script](#).

## 10.7. Controlling the query timeout

To set the query timeout in console mode, you can run the following statement

```
SQL> set timeout 42;
TIMEOUT set to 42
Execution time: 0.0s
SQL>
```

This will set a query timeout of 42 seconds. Note that not all JDBC drivers support a query timeout.

SET TIMEOUT has no effect when run as a [post-connect script](#).

## 10.8. Managing connection profiles

Connection profiles can be managed through several commands that are only available in console mode.

### 10.8.1. List available profiles - WbListProfiles

The command `WbListProfiles` will display a list of all displayed profiles

### 10.8.2. Delete a profile - WbDeleteProfile

You can delete an existing profile using the command `WbDeleteProfile`. The command takes one argument, which is the name of the profile. If the name is unique across all profile groups you don't have to specify a group name. If the name is not unique, you need to include the group name, e.g.

```
SQL> WbDeleteProfile {MyGroup}/SQL Server
Do you really want to delete the profile '{MyGroup}/SQL Server'? (Yes/No) yes
Profile '{MyGroup}/SQL Server' deleted
SQL>
```

As the profile name is the only parameter to this command, no quoting is necessary. Everything after the keyword `WbDeleteProfile` will be assumed to be the profile's name

All profiles are automatically saved after executing `WbDeleteProfile`.

### 10.8.3. Save the current profile - WbStoreProfile

Saves the currently active connection as a new connection profile. This can be used when SQL Workbench/J if the connection information was passed using individual parameters (`-url`, `-username` and so on) either on the commandline or through `WbConnect`.

```
SQL> WbStoreProfile {MyGroup}/PostgreSQL Production
Profile '{MyGroup}/PostgreSQL Production' added
SQL>
```

As the profile name is the only parameter to this command, no quoting is necessary. Everything after the keyword `WbDeleteProfile` will be assumed to be the profile's name. If there is already a profile with the same name, that profile is overwritten.

If the current connection references a JDBC driver that is not already defined, a new entry for the driver definitions is created referencing the library that was passed on the commandline.

All profiles are automatically saved after executing `WbStoreProfile`.

## 11. Export data using WbExport

The `WbExport` exports contents of the database into external files, e.g. plain text ("CSV") or XML.

The `WbExport` command can be used like any other SQL command (such as `UPDATE` or `INSERT`). This includes the usage in scripts that are run in [batch mode](#).

The `WbExport` command exports either the result of the **next** SQL Statement (which has to produce a result set) or the content of the table(s) specified with the `-sourceTable` parameter. The data is directly written to the output file and not loaded into memory. The export file(s) can be compressed ("zipped") on the fly. [WbImport](#) can import the zipped (text or XML) files directly without the need to unzip them.

If you want to save the data that is currently displayed in the result area into an external file, please use the [Save Data as](#) feature. You can also use the [Database Explorer](#) to export multiple tables.

When using a `SELECT` based export, you have to run both statements (`WbExport` and `SELECT`) as one script. Either select both statements in the editor and choose `SQL » Execute selected`, or make the two statements the only statements in the editor and choose `SQL » Execute all`.

You can also export the result of a `SELECT` statement, by selecting the statement in the editor, and then choose `SQL » Export query result`.

When exporting data into a Text or XML file, the content of BLOB columns is written into separate files. One file for each column of each row. Text files that are created this way can most probably only be imported using SQL Workbench/J as the main file will contain the filename of the BLOB data file instead of the actual BLOB data. The only other application that I know of, that can handle this type of imports is Oracle's `SQL*Loader` utility. If you run the text export together with the parameter `-writeoracleloader=true` the control file will contain the appropriate definitions to read the BLOB data from the external file.

### 11.1. Memory usage and WbExport

`WbExport` is designed to directly write the rows that are retrieved from the database to the export file without buffering them in memory.

Some JDBC drivers (e.g. PostgreSQL, jTDS and the Microsoft Driver) read the full result obtained from the database into memory. In that case, exporting large results might still require a lot of memory. Please refer to the chapter [Common problems](#) for details on how to configure the individual drivers if this happens to you.

### 11.2. Exporting Excel files

If you need to export data for Microsoft Excel, additional libraries are required to write the native Excel formats (xls and the new xlsx introduced with Office 2007). Exporting the "SpreadsheetML" format introduced with Office 2003 does not require additional libraries.

Before Build 108 `-type=xlsx` referred to the Office 2003 file format. To distinguish between the two (XML based) formats from Microsoft, the naming has been changed to reflect the default file extensions that are used by Microsoft.

SQL Workbench/J supports three different Excel file formats:

- Office 2003 (xlsm) - this is a plain XML format that does not need additional libraries
- The "old" binary format (xls) - only `poi.jar` is needed
- Office 2007 (xlsx) - additional libraries from the POI project are needed

Instead of downloading and renaming the POI libraries from the [Apache website](#), you can download all of them as a single archive from the SQL Workbench/J homepage: <http://www.sql-workbench.net/poi-add-on.zip>

Simply unzip the archive into the directory where `sqlworkbench.jar` is located.

## WbExport and the "Max. Rows" option

When you use the `WbExport` command together with a `SELECT` query, the "Max. Rows" setting will be **ignored** for the export.

### 11.3. General WbExport parameters

Parameter	Description
<code>-type</code>	<p>Possible values: <code>text</code>, <code>sqlinsert</code>, <code>sqlupdate</code>, <code>sqldeleteinsert</code>, <code>xml</code>, <code>ods</code>, <code>xlsm</code>, <code>xls</code>, <code>xlsx</code>, <code>html</code></p> <p>Defines the type of the output file. <code>sqlinsert</code> will create the necessary <code>INSERT</code> statements to put the data into a table. If the records may already exist in the target table but you don't want to (or cannot) delete the content of the table before running the generated script, SQL Workbench/J can create a <code>DELETE</code> statement for every <code>INSERT</code> statement. To create this kind of script, use the <code>sqldeleteinsert</code> type.</p> <p>In order for this to work properly the table needs to have keycolumns defined, or you have to define the keycolumns manually using the <code>-keycolumns</code> switch.</p> <p><code>sqlupdate</code> will generate <code>UPDATE</code> statements that update all non-key columns of the table. This will only generate valid <code>UPDATE</code> statements if at least one key column is present. If the table does not have key columns defined, or you want to use different columns, they can be specified using the <code>-keycolumns</code> switch.</p> <p><code>ods</code> will generate a spreadsheet file in the OpenDocument format that can be opened e.g. with OpenOffice.org.</p> <p><code>xlsm</code> will generate a spreadsheet file in the Microsoft Excel 2003 XML format ("SpreadsheetML"). This format has been introduced with build 108 as <code>xlsx</code> now selects the Office 2007 format.</p> <p><code>xls</code> will generate a spreadsheet file in the proprietary (binary) format for Microsoft Excel. The file <code>poi.jar</code> is required.</p> <p><code>xlsx</code> will generate a spreadsheet file in the Office Open XML format introduced with Microsoft Office 2007. Additional external libraries are required in order to be able to use this format. Please read the note at the beginning of this section.</p> <p style="text-align: center;"><code>xlsx</code></p>
<code>-file</code>	The output file to which the exported data is written. This parameter is ignored if <code>-outputDir</code> is also specified.
<code>-createDir</code>	If this parameter is set to true, SQL Workbench/J will create any needed directories when creating the output file.
<code>-sourceTable</code>	Defines a list of tables to be exported. If this switch is used, <code>-outputDir</code> is also required unless exactly one table is specified. If one table is specified, the <code>-file</code> parameter is used to generate the file for the table. If more than one table is specified, the <code>-outputDir</code> parameter is used to define the directory where the generated files should be stored. Each file will be named as the exported table with the appropriate extension ( <code>.xml</code> , <code>.sql</code> , etc). You can specify <code>*</code> as the table name which will then export all tables accessible by the current user.

Parameter	Description
	If you want to export tables from a different user or schema you can use a schema name combined with a wildcard e.g. <code>-sourceTable=otheruser.*</code> . In this case the generated output files will contain the schema name as part of the filename (e.g. <code>otheruser.person.txt</code> ). When <a href="#">importing</a> these files, SQL Workbench/J will try to import the tables into the schema/user specified in the filename. If you want to import them into a different user/schema, then you have to use the <code>-schema</code> switch for the <a href="#">import</a> command.
<code>-types</code>	Selects the object types to be exported. By default only TABLEs are exported. If you want to export the content of VIEWs or SYNONYMs as well, you have to specify all types with this parameter.  <code>-sourceTable=* -types=VIEW,SYNONYM</code> or <code>-sourceTable=T% -types=TABLE,VIEW,SYNONYM</code>
<code>-excludeTables</code>	The tables listed in this parameter will not be exported. This can be used when all but a few tables should be exported from a schema. First all tables specified through <code>-sourceTable</code> will be evaluated. The tables specified by <code>-excludeTables</code> can include wildcards in the same way, <code>-sourceTable</code> allows wildcards.  <code>-sourceTable=* -excludeTables=TEMP*</code> will export all tables, but not those starting with TEMP.
<code>-sourceTablePrefix</code>	Define a common prefix for all tables listed with <code>-sourceTable</code> . When this parameter is specified the existence of each table is not tested any longer (as it is normally done).  When this parameter is specified the generated statement for exporting the table is changed to a <code>SELECT * FROM [prefix]tableName</code> instead of listing all columns individually.  This can be used when exporting views on tables, when for each table e.g. a view with a certain prefix exists (e.g. table PERSON has the view V_PERSON and the view does some filtering of the data).
<code>-outputDir</code>	When using the <code>-sourceTable</code> switch with multiple tables, this parameter is mandatory and defines the directory where the generated files should be stored.
<code>-continueOnError</code>	When exporting more than one table, this parameter controls whether the whole export will be terminated if an error occurs during export of one of the tables.
<code>-encoding</code>	Defines the encoding in which the file should be written. Common encodings are ISO-8859-1, ISO-8859-15, UTF-8 (or UTF8). To get a list of available encodings, execute <code>WbExport</code> with the parameter <code>-showencoding</code> . This parameter is ignored for XLS, XLSX and ODS exports.
<code>-showEncodings</code>	Displays the encodings supported by your Java version and operating system. If this parameter is present, all other parameters are ignored.
<code>-lineEnding</code>	Possible values are: <code>cr lf</code> , <code>lf</code>  Defines the line ending to be used for XML or text files. <code>cr lf</code> puts the ASCII characters #13 and #10 after each line. This is the standard format on Windows based systems. <code>dos</code> and <code>win</code> are synonym values for <code>cr lf</code> , <code>unix</code> is a synonym for <code>lf</code> .  <code>lf</code> puts only the ASCII character #10 at the end of each line. This is the standard format on Unix based systems ( <code>unix</code> is a synonym value for this format).  The default line ending used depends on the platform where SQL Workbench/J is running.
<code>-header</code>	Possible values: <code>true</code> , <code>false</code>

Parameter	Description
	If this parameter is set to true, the header (i.e. the column names) are placed into the first line of output file. The default is to not create a header line. You can define the default value for this parameter in the file <a href="#">workbench.settings</a> . This parameter is valid for text and spreadsheet (OpenDocument, Excel) exports.
-compress	<p>Selects whether the output file should be compressed and put into a ZIP archive. An archive will be created with the name of the specified outputfile but with the extension <code>.zip</code>. The archive will then contain the specified file (e.g. if you specify <code>data.txt</code>, an archive <code>data.zip</code> will be created containing exactly one entry with the name <code>data.txt</code>). If the exported result set contains BLOBs, they will be stored in a separate archive, named <code>data_lobs.zip</code>.</p> <p>When exporting multiple tables using the <code>-sourcetable</code> parameter, then SQL Workbench/J will create one ZIP archive for each table in the specified output directory with the filename "<code>tablename</code>".<code>.zip</code>. For any table containing BLOB data, one additional ZIP archive is created.</p>
-tableWhere	Defines an additional WHERE clause that is appended to all SELECT queries to retrieve the rows from the database. No validation check will be done for the syntax or the columns in the where clause. If the specified condition is not valid for all exported tables, the export will fail.
-clobAsFile	<p>Possible values: <code>true</code>, <code>false</code></p> <p>For SQL, XML and Text export this controls how the contents of CLOB fields are exported. Usually the CLOB content is put directly into the output file. When generating SQL scripts with <code>WbExport</code> this can be a problem as not all DBMS can cope with long character literals (e.g. Oracle has a limit of 4000 bytes). When this parameter is set to true, SQL Workbench/J will create one file for each CLOB column value. This is the same behaviour as with BLOB columns.</p> <p>Text files that are created with this parameter set to true, will contain the filename of the generated output file instead of the actual column value. When importing such a file using <code>WbImport</code> you have to specify the <code>-clobIsFilename=true</code> parameter. Otherwise the filenames will be stored in the database and not the clob data. This parameter is not necessary when importing XML exports, as <code>WbImport</code> will automatically recognize the external files.</p> <p>Note that SQL exports (<code>-type=sqlinsert</code>) generated with <code>-clobAsFile=true</code> can only be run with SQL Workbench/J!</p> <p>All CLOB files that are written using the encoding specified with the <code>-encoding</code> switch. If the <code>-encoding</code> parameter is not specified the <a href="#">default file encoding</a> will be used.</p>
-lobIdCols	When exporting CLOB or BLOB columns as external files, the filename with the LOB content is generated using the row and column number for the currently exported LOB column (e.g. <code>data_r15_c4.data</code> ). If you prefer to have the value of a unique column combination as part of the file name, you can specify those columns using the <code>-lobIdCols</code> parameter. The filename for the LOB will then be generated using the base name of the export file, the column name of the LOB column and the values of the specified columns. If you export your data into a file called <code>user_info</code> and specify <code>-lobIdCols=id</code> and your result contains a column called <code>img</code> , the LOB files will be named e.g. <code>user_info_img_344.data</code>

Parameter	Description
-lobsPerDirectory	<p>When exporting CLOB or BLOB columns as external files, the generated files can be distributed over several directories to avoid an excessive number of files in a single directory. The parameter <code>lobsPerDirectory</code> defines how many LOB files are written into a single directory. When the specified number of files have been written, a new directory is created. The directories are always created as a sub-directory of the target directory. The name for each directory is the base export filename plus "_lobs" plus a running number. So if you export the data into a file "the_big_table.txt", the LOB files will be stored in "the_big_table_lob_1", "the_big_table_lob_2", "the_big_table_lob_3" and so on.</p> <p>The directories will be created if needed, but if the directories already exist (e.g. because of a previous export) <b>their contents will not be deleted!</b></p>
-extensionColumn	<p>When exporting CLOB or BLOB columns as external files, the extension of the generated filenames can be defined based on a column of the result set. If the exported table contains more than one type of BLOBs (e.g. JPEG, GIF, PDF) and your table stores the information to define the extension based on the contents, this can be used to re-generate proper filenames.</p> <p>This parameter only makes sense if exactly one BLOB column of a table is exported.</p>
-filenameColumn	<p>When exporting CLOB or BLOB columns as external files, the complete filename can be taken from a column of the result set (instead of dynamically creating a new file name based on the row and column numbers).</p> <p>This parameter only makes sense if exactly one BLOB column of a table is exported.</p>
-append	<p>Possible values: <code>true</code>, <code>false</code></p> <p>Controls whether results are appended to an existing file, or overwrite an existing file. This parameter is only supported for text or SQL export types.</p>
-dateFormat	<p>The date <a href="#">format</a> to be used when writing date columns into the output file. This parameter is ignored for SQL exports.</p>
-timestampFormat	<p>The <a href="#">format</a> to be used when writing datetime (or timestamp) columns into the output file. This parameter is ignored for SQL exports.</p>
-blobType	<p>Possible values: <code>file</code>, <code>dbms</code>, <code>ansi</code>, <code>base64</code></p> <p>This parameter controls how BLOB data will be put into the generated SQL statements. By default no conversion will be done, so the actual value that is written to the output file depends on the JDBC driver's implementation of the Blob interface. It is only valid for Text, SQL and XML exports, although not all parameter values make sense for all export types.</p> <p>The type <code>base64</code> is primarily intended for Text exports (e.g. to be used with PostgreSQL's <code>COPY</code> command)</p> <p>The types <code>dbms</code> and <code>ansi</code> are intended for SQL exports and generate a representation of the binary data as part of the SQL statement. <code>DBMS</code> will use a format that is understood by the DBMS you are exporting from, while <code>ansi</code> will generate a standard hex based representation of the binary data. The syntax generated by the <code>ansi</code> format is not understood by all DBMS!</p>

Parameter	Description
	<p>Two additional SQL literal formats are available that can be used together with PostgreSQL: <code>pgDecode</code> and <code>pgEscape</code>. <code>pgDecode</code> will generate a hex representation using PostgreSQL's <a href="#">decode()</a> function. Using <code>decode</code> is a very compact format. <code>pgEscape</code> will use PostgreSQL's <a href="#">escaped octets</a>, and generates much bigger statements (due to the increase escaping overhead).</p> <p>When using <code>file</code>, <code>base64</code> or <code>ansi</code> the file can imported using <a href="#">WbImport</a></p> <p>The parameter value <code>file</code>, will cause SQL Workbench/J to write the contents of each blob column into a separate file. The SQL statement will contain the SQL Workbench/J specific extension to read the blob data from the file. For details please refer to BLOB support. If you are planning to run the generated SQL scripts using SQL Workbench/J this is the recommended format.</p> <p>Note that SQL scripts generated with <code>-blobType=file</code> can only be run with SQL Workbench/J</p> <p>The parameter value <code>ansi</code>, will generate "binary strings" that are compatible with the ANSI definition for binary data. MySQL and Microsoft SQL Server support these kind of literals.</p> <p>The parameter value <code>dbms</code>, will create a DBMS specific "binary string". MySQL, HSQLDB, H2 and PostgreSQL are known to support literals for binary data. For other DBMS using this option will still create an ansi literal but this might result in an invalid SQL statement.</p>
<code>-replaceExpression -replaceWith</code>	<p>Using these parameters, arbitrary text can be replaced during the export. <code>-replaceExpression</code> defines the regular expression that is to be replaced. <code>-replaceWith</code> defines the replacement value. <code>-replaceExpression='(\n \r\n)'</code> <code>-replaceWith=' '</code> will replace all newline characters with a blank.</p> <p>The search and replace is done on the "raw" data retrieved from the database before the values are converted to the corresponding output format. In particular this means replacing is done before any <a href="#">character escaping</a> takes place.</p> <p>Because the search and replace is done before the data is converted to the output format, it can be used for all export types. Only character columns (CHAR, VARCHAR, CLOB, LONGVARCHAR) are taken into account.</p>
<code>-showProgress</code>	<p>Valid values: true, false, &lt;numeric value&gt;</p> <p>Control the update frequency in the statusbar (when running in GUI mode). The default is every 10th row is reported. To disable the display of the progress specify a value of 0 (zero) or the value false. true will set the progress interval to 1 (one).</p>

## 11.4. Parameters for text export

Parameter	Description
<code>-delimiter</code>	The given string sequence will be placed between two columns. The default is a tab character ( <code>-delimiter=\t</code> )
<code>-rowNumberColumn</code>	If this parameter is specified with a value, the value defines the name of an additional column that will contain the rownumber. The row number will always be exported as the first column. If the text file is not created with a header ( <code>-header=false</code> ) a value must still be provided to enable the creation of the additional column.

Parameter	Description
-quoteChar	The character (or sequence of characters) to be used to enclose text (character) data if the delimiter is contained in the data. By default quoting is disabled until a quote character is defined. To set the double quote as the quote character you have to enclose it in single quotes: <code>-quotechar='\"'</code>
-quoteCharEscaping	<p>Possible values: none, escape, duplicate</p> <p>Defines how quote characters that appear in the actual data are written to the output file.</p> <p>If no quote character has been defined using the <code>-quoteChar</code> switch, this option is ignored.</p> <p>If <code>escape</code> is specified a quote character (defined through <code>-quoteChar</code>) that is embedded in the exported (character) data is written as e.g. <code>here is a \" quote character</code>.</p> <p>If <code>duplicate</code> is specified, a quote character (defined through <code>-quoteChar</code>) that is embedded in the exported (character) data is written as two quotes e.g. <code>here is a \" quote character</code>.</p>
-quoteAlways	<p>Possible values: true, false</p> <p>If quoting is enabled (via <code>-quoteChar</code>, then character data will normally only be quoted if the delimiter is found inside the actual value that is written to the output file. If <code>-quoteAlways=true</code> is specified, character data will always be enclosed in the specified quote character. This parameter is ignored if not quote character is specified. If you expect the quote character to be contained in the values, you should enable character escaping, otherwise the quote character that is part of the exported value will break the quote during import.</p> <p>NULL values will not be quoted even if this parameter is set to true. This is useful to distinguish between NULL values and empty strings.</p>
-decimal	The decimal symbol to be used for numbers. The default is a dot (e.g. 3.14152)
-escapeText	<p>This parameter controls the escaping of non-printable or non-ASCII characters. Valid options are <code>ctrl</code> which will escape everything below ASCII 32 (newline, tab, etc), <code>7bit</code> which will escape everything below ASCII 32 and above 126, <code>8bit</code> which will escape everything below ASCII 32 and above 255 and <code>extended</code> which will escape everything outside the range [32-126] and [161-255]</p> <p>This will write a unicode representation of the character into the text file e.g. <code>\n</code> for a newline, <code>\u00F6</code> for <code>ö</code>. This file can only be imported using SQL Workbench/J (at least I don't know of any DBMS specific loader that will decode this properly)</p> <p>If character escaping is enabled, then the quote character will be escaped inside quoted values and the delimiter will be escaped inside non-quoted values. The delimiter could also be escaped inside a quoted value if the delimiter falls into the selected escape range (e.g. a tab character).</p>
-formatFile	<p>Possible values: postgres, oracle, sqlserver, db2</p> <p>This parameter controls the creation of a control file for the bulk load utilities of Oracle and Microsoft SQL Server. <code>oracle</code> will create a control file for Oracle's SQL*Loader utility, <code>sqlserver</code> will create a format file for Microsoft's bcp utility. The format file has the same filename as the output file but with the ending <code>.ctl</code> for Oracle and <code>.fmt</code> for SQL Server. For PostgreSQL, this will create the necessary COPY syntax to import the generated text file. For DB2 this will create an IMPORT command to import the exported data.</p>

Parameter	Description
	<p>You can specify several formats at the same time. In that case one control file for each format specified will be created.</p> <p>The generated format file(s) are intended as a starting point for your own adjustments. Don't expect them to be complete specifying all possible options.</p>

## 11.5. Parameters for XML export

Parameter	Description
-table	The given tablename will be put into the <table> tag as an attribute.
-decimal	The decimal symbol to be used for numbers. The default is a dot (e.g. 3.14152)
-useCDATA	<p>Possible values: true, false</p> <p>Normally all data written into the xml file will be written with escaped XML characters (e.g. &lt; will be written as &amp;lt;). If you don't want that escaping, set -useCDATA=true and all character data (VARCHAR, etc) will be enclosed in a CDATA section.</p> <p>With -useCDATA=true a HTML value would be written like this:</p> <pre>&lt;![CDATA[&lt;b&gt;This is a title&lt;/b&gt;]]&gt;</pre> <p>With -useCDATA=false (the default) a HTML value would be written like this:</p> <pre>&amp;lt;b&amp;gt;This is a title&amp;lt;/b&amp;gt;</pre>
-stylesheet	The name of the XSLT stylesheet that should be used to transform the SQL Workbench/J specific XML file into a different format. If -stylesheet is specified, -xsltoutput has to be specified as well.
-xsltOutput	The resulting output file (specified with the -file parameter), can be transformed using XSLT after the export has finished. This parameter then defines the name of the outputfile of the transformation.
-verboseXML	<p>Possible values: true, false</p> <p>This parameter controls the tags that are used in the XML file and minor formatting features. The default is -verboseXML=true and this will generate more readable tags and formatting. However the overhead imposed by this is quite high. Using -verboseXML=false uses shorter tag names (not longer than two characters) and does put more information in one line. This output is harder to read for a human but is smaller in size which could be important for exports with large result sets.</p>

## 11.6. Parameters for type SQLUPDATE, SQLINSERT or SQLDELETEINSERT

Parameter	Description
-table	Define the tablename to be used for the UPDATE or INSERT statements. This parameter is required if the SELECT statement has multiple tables in the FROM list. table.
-charfunc	<p>If this parameter is given, any non-printable character in a text/character column will be replaced with a call to the given function with the ASCII value as the parameter.</p> <p>If -charfunc=chr is given (e.g. for an Oracle syntax), a CR (=13) inside a character column will be replaced with:</p>

Parameter	Description
	<p>INSERT INTO ... VALUES ( 'First line'    chr(13)    'Second line' ... )</p> <p>This setting will affect ASCII values from 0 to 31</p>
-concat	<p>If the parameter <code>-charfunc</code> is used SQL Workbench/J will concatenate the individual pieces using the ANSI SQL operator for string concatenation. In case your DBMS does not support the ANSI standard (e.g. MS ACCESS) you can specify the operator to be used: <code>-concat=+</code> defines the plus sign as the concatenation operator.</p>
-sqlDateLiterals	<p>Possible values: <code>jdbc</code>, <code>ansi</code>, <code>dbms</code>, <code>default</code></p> <p>This parameter controls the generation of date or timestamp literals. By default literals that are specific for the current DBMS are created. You can also choose to create literals that comply with the JDBC specification or ANSI SQL literals for dates and timestamps.</p> <p><b><code>jdbc</code></b> selects the creation of JDBC compliant literals. These should be usable with every JDBC based tool, including your own Java code: { <code>d '2004-04-28'</code> } or { <code>ts '2002-04-02 12:02:00.042'</code> }. This is the recommended format if you plan to use SQL Workbench/J (or any other JDBC based tool) to run the generated statements.</p> <p><b><code>ansi</code></b> selects the creation of ANSI SQL compliant date literals: <code>DATE '2004-04-28'</code> or <code>TIMESTAMP '2002-04-02 12:04:00'</code>. Please consult the manual of the target DBMS, to find out whether it supports ANSI compliant date literals.</p> <p><b><code>default</code></b> selects the creation of quoted date and timestamp literals in ISO format (e.g. '2004-04-28'). Several DBMS support this format (e.g. PostgreSQL, Microsoft SQL Server)</p> <p><b><code>dbms</code></b> selects the creation of specific literals to be used with the current DBMS (using e.g. the <code>to_date()</code> function for Oracle). The format of these literals can be customized if necessary in <code>workbench.settings</code> using the keys <code>workbench.sql.literals.[type].[datatype].pattern</code> where <code>[type]</code> is the type specified with this parameter and <code>[datatype]</code> is one of <code>time</code>, <code>date</code>, <code>timestamp</code>. If you add new literal types, please also adjust the key <code>workbench.sql.literals.types</code> which is used to show the possible values in the GUI (auto-completion "Save As" dialog, Options dialog). If no type is specified (or <code>dbms</code>), SQL Workbench/J first looks for an entry where <code>[type]</code> is the current <a href="#">dbid</a>. If no value is found, <code>default</code> is used.</p> <p>You can define the default literal format to be used for the <code>WbExport</code> command in the <a href="#">options dialog</a>.</p>
-commitEvery	<p>A numeric value which identifies the number of INSERT or UPDATE statements after which a COMMIT is put into the generated SQL script.</p> <p><code>-commitevery=100</code></p> <p>will create a <code>COMMIT;</code> after every 100th statement.</p> <p>If this is not specified one <code>COMMIT;</code> will be added at the end of the script. To suppress the final <code>COMMIT</code>, you can use <code>-commitEvery=none</code>. Passing <code>-commitEvery=atEnd</code> is equivalent to <code>-commitEvery=0</code></p>
-createTable	<p>Possible values: <code>true</code>, <code>false</code></p> <p>If this parameter is set to <code>true</code>, the necessary <code>CREATE TABLE</code> command is put into the output file. This parameter is ignored when creating <code>UPDATE</code> statements.</p>
-useSchema	<p>Possible values: <code>true</code>, <code>false</code></p>

Parameter	Description
	If this parameter is set to <code>true</code> , all table names are prefixed with the appropriate schema. The default is taken from the global option <a href="#">Include owner in export</a>
-keyColumns	<p>A comma separated list of column names that occur in the table or result set that should be used as the key columns for UPDATE or DELETE</p> <p>If the table does not have key columns, or the source SELECT statement uses a join over several tables, or you do not want to use the key columns defined in the database, this key can be used to define the key columns to be used for the UPDATE statements. This key overrides any key columns defined on the base table of the SELECT statement.</p>

## 11.7. Parameters for Spreadsheet types (ods, xslm, xls, xlsx)

Parameter	Description
-title	The name to be used for the worksheet
-infoSheet	<p>Possible values: <code>true</code>, <code>false</code></p> <p>If set to <code>true</code>, a second worksheet will be created that contains the generating SQL of the export. For ods exports, additional export information is available in the document properties.</p> <p>Default value: <code>false</code></p>
-fixedHeader	<p>Possible values: <code>true</code>, <code>false</code></p> <p>If set to <code>true</code>, the header row will be "frozen" in the Worksheet so that it will not scroll out of view.</p> <p>Default value: <code>true</code></p>
-autoFilter	<p>Possible values: <code>true</code>, <code>false</code></p> <p>If set to <code>true</code>, the "auto-filter" feature for the column headers will be turned on. This is only valid for ODS and XLSM exports. It is not supported for XLS or XLSX.</p> <p>Default value: <code>true</code></p>

## 11.8. Parameters for HTML export

Parameter	Description
-createFullHTML	<p>Possible values: <code>true</code>, <code>false</code></p> <p>Default value: <code>true</code></p> <p>If this is set to <code>true</code>, a full HTML page (including <code>&lt;html&gt;</code>, <code>&lt;body&gt;</code> tags) will be created.</p>
-escapeHTML	<p>Possible values: <code>true</code>, <code>false</code></p> <p>Default value: <code>true</code></p> <p>If this is set to <code>true</code>, values inside the data will be escaped (e.g. the <code>&lt;</code> sign will be written as <code>&amp;lt;</code>) so that they are rendered properly in an HTML page. If your data contains HTML tag that should be saved as HTML tags to the output, this parameter must be <code>false</code>.</p>

Parameter	Description
-title	The title for the HTML page (put into the <title> tag of the generated output)
-preDataHtml	<p>With this parameter you can specify a HTML chunk that will be added before the export data is written to the output file. This can be used to e.g. create a heading for the data: -preDataHtml='&lt;h1&gt;List of products&lt;/h1&gt;'.</p> <p>The value will be written to the output file "as is". Any escaping of the HTML must be provided in the parameter value.</p>
-postDataHtml	With this parameter you can specify a HTML chunk that will be added after the data has been written to the output file.

## 11.9. Compressing export files

The `WbExport` command supports compressing of the generated output files. This includes the "main" export file as well as any associated LOB files.

When using [WbImport](#) you can import the data stored in the archives without unpacking them. Simply specify the archive name with the `-file` parameter. SQL Workbench/J will detect that the input file is an archive and will extract the information "on the fly". Assume the following export command:

```
WbExport -type=text -file=/home/data/person.txt -compress=true -sourcetable=person;
```

This command will create the file `/home/data/person.zip` that will contain the specified `person.txt`. To import this export into the table `employee`, you can use the following command:

```
WbImport -type=text -file=/home/data/person.zip -table=employee;
```

Assuming the `PERSON` table had a BLOB colum (e.g. a picture of the person), the `WbExport` command would have created an additional file called `person_blobs.zip` that would contain all BLOB data. The `WbImport` command will automatically read the BLOB data from that archive.

## 11.10. Examples

### 11.10.1. Simple plain text export

```
WbExport -type=text
        -file='c:/data/data.txt'
        -delimiter='|'
        -decimal=', '
        -sourcetable=data_table;
```

Will create a text file with the data from `data_table`. Each column will be separated with the character `|` Each fractional number will be written with a comma as the decimal separator.

### 11.10.2. Exporting multiple tables

```
WbExport -type=text
        -outputDir='c:/data'
        -delimiter=';'
        -header=true
        -sourcetable=table_1, table_2, table_3, table_4;
```

This will export each specified table into a text file in the specified directory. The files are named "table\_1.txt", "table\_2.txt" and so on.

Limiting the export data when using a table based export, can be done using the `-tableWhere` argument. This requires that the specified WHERE condition is valid for all tables, e.g. when every table has a column called `MODIFIED_DATE`

```
WbExport -type=text
         -outputDir='c:/data'
         -delimiter=';'
         -header=true
         -tableWhere="WHERE modified_date > DATE '2009-04-02'"
         -sourcetable=table_1, table_2, table_3, table_4;
```

This will add the specified where clause to **each** SELECT, so that only rows are exported that were changed after April 2nd, 2009

### 11.10.3. Export based on a SELECT statement

```
WbExport -type=text
         -file='c:/data/data.txt'
         -delimiter=', '
         -decimal=', '
         -dateFormat='yyyy-MM-dd';
SELECT * FROM data_table;
```

### 11.10.4. Export a complete schema

To export all tables from the current connection into tab-separated files and compress the files, you can use the following statement:

```
WbExport -type=text
         -outputDir=c:/data/export
         -compress=true
         -sourcetable=*;
```

This will create one zip file for each table containing the exported data as a text file. If a table contains BLOB columns, the blob data will be written into a separate zip file.

The files created by the above statement can be imported into another database using the following command:

```
WbImport -type=text
         -sourceDir=c:/data/export
         -checkDependencies=true;
```

### 11.10.5. Export as SQL INSERT script

To generate a file that contains INSERT statements that can be executed on the target system, the following command can be used:

```
WbExport -type=sqlinsert
         -file='c:/data/newtable.sql'
         -table=newtable;
SELECT * FROM table1, table2
WHERE table1.column1 = table2.column1;
```

will create a SQL script which that contains statements like `INSERT INTO newtable (...) VALUES (...);` and the list of columns are all columns that are defined by the `SELECT` statement.

If the parameter `-table` is omitted, the creation of SQL `INSERT` statements is only possible, if the `SELECT` is based on a single table (or view).

### 11.10.6. Exporting LOB data

To extract the contents of CLOB columns you have to specify the parameter `-clobAsFile=true`, otherwise the contents of the CLOB columns will be written directly into the export file. BLOB columns will always be exported into separate tables.

When exporting tables that contain BLOB columns, one file for each blob column and row will be created. By default the generated filenames will contain the row and column number to make the names unique. You can however control the creation of filenames when exporting LOB columns using several different approaches. If a unique name is stored within the table you can use the `-filenameColumn` parameter to generate the filenames based on the contents of that column:

```
WbExport -file='c:/temp/blob_table.txt'
        -type=text
        -delimiter=', '
        -filenameColumn=file_name;
```

Will create the file `blob_table.txt` and for each blob a file where the name is retrieved from the column `BLOB_TABLE.FILE_NAME`. Note that if the filename column is not unique, blob files will be overwritten without an error message.

You can also base the export on a `SELECT` statement and then generate the filename using several columns:

```
WbExport -file='c:/temp/blob_table.txt'
        -type=text
        -delimiter=', '
        -filenameColumn=fname;
SELECT blob_column, 'data_' || id_column || '_' || some_name || '.' || type_column as fname
FROM blob_table;
```

This examples assumes that the following columns are part of the table `blob_table`: `id_column`, `some_name` and `type_column`. The filenames for the blob of each row will be taken from the computed column `fname`. To be able to reference the column in the `WbExport` you must give it an alias.

This approach assumes that only a single blob column is exported. When exporting multiple blob columns from a single table, it's only possible to create unique filenames using the row and column number (the default behaviour).

### 11.10.7. Replace data during export

When writing the export data, values in character columns can be replaced using regular expressions.

```
WbExport -file='/path/to/export.tx'
        -type=text
        -replaceExpression='(\n|\r\n)' -replaceWith='*'
        -sourceTable=export_table;
```

This will replace each newline (either DOS CR/LF or Unix LF) with the character `*`.

The value for `-replaceExpression` defines a regular expression. In the example above multiple new lines will be replace with multiple `*` characters. To replace consecutive new lines with a single `*` character, use the regular expression `-replaceExpression='(\n|\r\n)+'`. (Note the `+` sign after the brackets)

## 12. Import data using WbImport

The `WbImport` command can be used to import data from text or XML files into a table of the database. `WbImport` can read the XML files generated by the `WbExport` command's XML format. It can also read text files created by the `WbExport` command that escape non-printable characters.

The `WbImport` command can be used like any other SQL command (such as `UPDATE` or `INSERT`), including scripts that are run in [batch mode](#).

During the import of text files, empty lines (i.e. lines which only contain whitespace) will be silently ignored.

`WbImport` recognizes certain "literals" to identify the current date or time when converting values from text files to the appropriate data type of the DBMS. Thus, input values like `now`, or `current_timestamp` for date or timestamp columns are converted correctly. For details on which "literals" are supported, please see the description about [editing data](#) [43].

The [DataPumper](#) can also be used to import text files into a database table, though it does not offer all of the possibilities from the `WbImport` command.

Archives created with the `WbExport` command using the `-compress=true` parameter can be imported using `WbImport` command. You simply need to specify the archive file created by `WbExport`, and `WbImport` will automatically detect the archive. For an example to create and import compressed exports, please refer to [compressing export files](#)

If you use `continueOnError=true` and expect a substantial number of rows to fail, it is highly recommended to also use a "bad file" to log all rejected records. Otherwise the rejected records are stored in memory (until the import finishes) which may lead to an out of memory error.

### 12.1. General parameters

The `WbImport` command has the following syntax

Parameter	Description
<code>-type</code>	Possible values: <code>xml</code> , <code>text</code>  Defines the type of the input file
<code>-mode</code>	Defines how the data should be sent to the database. Possible values are 'INSERT', 'UPDATE', 'INSERT , UPDATE' and 'UPDATE , INSERT' For details please refer to the <a href="#">update mode</a> explanation.
<code>-file</code>	Defines the full name of the input file. Alternatively you can also specify a directory (using <code>-sourcedir</code> ) from which all files are imported.
<code>-table</code>	Defines the table into which the data should be imported  This parameter is ignored, if the files are imported using the <code>-sourcedir</code> parameter
<code>-sourceDir</code>	Defines a directory which contains import files. All files from that directory will be imported. If this switch is used with text files and no target table is specified, then it is assumed that each filename (without the extension) defines the target table. If a target table is specified using the <code>-table</code> parameter, then all files will be imported into the same table. The <code>-deleteTarget</code> will be ignored if multiple files are imported into a single table.
<code>-extension</code>	When using the <code>-sourcedir</code> switch, the extension for the files can be defined. All files ending with the supplied value will be processed. (e.g. <code>-extension=csv</code> ). The extension given is case-sensitiv (i.e. <code>TEXT</code> is something different than <code>txt</code> )

Parameter	Description
-ignoreOwner	If the file names imported with from the directory specified with -sourceDir contain the owner (schema) information, this owner (schema) information can be ignored using this parameter. Otherwise the files might be imported into a wrong schema, or the target tables will not be found.
-excludeFiles	Using -excludeFiles, files from the source directory (when using -sourceDir) can be excluded from the import. The value for this parameter is a comma separated list of partial names. Each file that contains at least one of the values supplied in this parameter is ignored. -excludeFiles=back,data will exclude any file that contains the value back or data in it, e.g.: backup, to_back, log_data_store etc.
-checkDependencies	When importing more than one file (using the -sourcedir switch), into tables with foreign key constraints, this switch can be used to import the files in the correct order (child tables first). When -checkDependencies=true is passed, SQL Workbench/J will check the foreign key dependencies for all tables. Note that this will not check dependencies in the data. This means that e.g. the data for a self-referencing table (parent/child) will not be order so that it can be imported. To import self-referencing tables, the foreign key constraint should be set to "initially deferred" in order to postpone evaluation of the constraint until commit time.
-commitEvery	<p>If your DBMS needs frequent commits to improve performance and reduce locking on the import table you can control the number of rows after which a COMMIT is sent to the server.</p> <p>-commitEvery is numeric value that defines the number of rows after which a COMMIT is sent to the DBMS. If this parameter is not passed (or a value of zero or lower), then the import is run as a single transaction that is committed at the end.</p> <p>When using <a href="#">batch import</a> and your DBMS requires frequent commits to improve import performance, the -commitBatch option should be used instead.</p> <p>You can turn off the use of a commit or rollback during import completely by using the option -transactionControl=false.</p> <p>Using -commitEvery means, that in case of an error the already imported rows cannot be rolled back, leaving the data in a potential invalid state.</p>
-transactionControl	<p>Possible values: true, false</p> <p>Controls if SQL Workbench/J handles the transaction for the import, or if the import must be committed (or rolled back) manually. If -transactionControl=false is specified, SQL Workbench/J will neither send a COMMIT nor a ROLLBACK at the end. This can be used when multiple files need to be imported in a single transaction. This can be combined with the <a href="#">cleanup</a> and <a href="#">error</a> scripts in batch mode.</p>
-continueOnError	<p>Possible values: true, false</p> <p>This parameter controls the behaviour when errors occur during the import. The default is true, meaning that the import will continue even if an error occurs during file parsing or updating the database. Set this parameter to false if you want to stop the import as soon as an error occurs.</p> <p>The default value for this parameter can be controlled in the <a href="#">settings file</a> and it will be displayed if you run WbImport without any parameters.</p> <p>With PostgreSQL continueOnError will only work, if the use of savepoints is enabled using -useSavepoint=true.</p>
-useSavepoint	Possible values: true, false

Parameter	Description
	<p>Controls if SQL Workbench/J guards every insert or update statement with a savepoint to recover from individual error during import, when <code>continueOnError</code> is set to <code>true</code>.</p> <p>Using a savepoint for each DML statement can drastically reduce the performance of the import.</p>
<code>-keyColumns</code>	<p>Defines the key columns for the target table. This parameter is only necessary if import is running in <code>UPDATE</code> mode.</p> <p>This parameter is ignored if files are imported using the <code>-sourcedir</code> parameter</p>
<code>-schema</code>	Defines the schema into which the data should be imported. This is necessary for DBMS that support schemas, and you want to import the data into a different schema, then the current one.
<code>-encoding</code>	Defines the encoding of the input file (and possible CLOB files)
<code>-deleteTarget</code>	<p>Possible values: <code>true</code>, <code>false</code></p> <p>If this parameter is set to <code>true</code>, data from the target table will be deleted (using <code>DELETE FROM . . .</code>) before the import is started. This parameter will only be used if <code>-mode=insert</code> is specified.</p>
<code>-truncateTable</code>	<p>Possible values: <code>true</code>, <code>false</code></p> <p>This is essentially the same as <code>-deleteTarget</code>, but will use the command <code>TRUNCATE</code> to delete the contents of the table. For those DBMS that support this command, deleting rows is usually faster compared to the <code>DELETE</code> command, but it cannot be rolled back. This parameter will only be used if <code>-mode=insert</code> is specified.</p>
<code>-batchSize</code>	<p>A numeric value that defines the size of the batch queue. Any value greater than 1 will enable batch mode. If the JDBC driver supports this, the <code>INSERT</code> (or <code>UPDATE</code>) performance can be increased drastically.</p> <p>This parameter will be ignored if the driver does not support batch updates or if the mode is not <code>UPDATE</code> or <code>INSERT</code> (i.e. if <code>-mode=update, insert</code> or <code>-mode=insert, update</code> is used).</p>
<code>-commitBatch</code>	<p>Possible values: <code>true</code>, <code>false</code></p> <p>If using batch execution (by specifying a batch size using the <code>-batchSize</code> parameter) each batch will be committed when this parameter is set to <code>true</code>. This is slightly different to using <code>-commitEvery</code> with the value of the <code>-batchSize</code> parameter. The latter one will add a <code>COMMIT</code> statement to the batch queue, rather than calling the JDBC <code>commit()</code> method. Some drivers do not allow to add different statements in a batch queue. So, if a frequent <code>COMMIT</code> is needed, this parameter should be used.</p> <p>When you specify <code>-commitBatch</code> the parameter <code>-commitEvery</code> will be ignored. If no batch size is given (using <code>-batchSize</code>, then <code>-commitBatch</code> will also be ignored.</p>
<code>-updateWhere</code>	When using <a href="#">update mode</a> an additional <code>WHERE</code> clause can be specified to limit the rows that are updated. The value of the <code>-updatewhere</code> parameter will be added to the generated <code>UPDATE</code> statement. If the value starts with the keyword <code>AND</code> or <code>OR</code> the value will be added without further changes, otherwise the value will be added as an <code>AND</code> clause enclosed in brackets. This parameter will be ignored if update mode is not active.
<code>-startRow</code>	A numeric value to define the first row to be imported. Any row before the specified row will be ignored. The header row is not counted to determine the row number. For a text file with a header row, the physical line 2 is row 1 (one) for this parameter.

Parameter	Description
	When importing text files, empty lines in the input file are silently ignored and do not add to the count of rows for this parameter. So if your input file has two lines to be ignored, then one empty line and then another line to be ignored, <code>startRow</code> must be set to 4.
<code>-endRow</code>	A numeric value to define the last row to be imported. The import will be stopped after this row has been imported. When you specify <code>-startRow=10</code> and <code>-endRow=20</code> 11 rows will be imported (i.e. rows 10 to 20). If this is a text file import with a header row, this would correspond to the physical lines 11 to 21 in the input file as the header row is not counted.
<code>-badFile</code>	<p>Possible values: <code>true</code>, <code>false</code></p> <p>If <code>-continueOnError=true</code> is used, you can specify a file to which rejected rows are written. If the provided filename denotes a directory a file with the name of the import table will be created in that directory. When doing multi-table inserts you <b>have</b> to specify a directory name.</p> <p>If a file with that name exists it will be deleted when the import for the table is started. The file will not be created unless at least one record is rejected during the import. The file will be created with the same encoding as indicated for the input file(s).</p>
<code>-maxLength</code>	<p>With the parameter <code>-maxLength</code> you can truncate data for character columns (VARCHAR, CHAR) during import. This can be used to import data into columns that are not big enough (e.g. VARCHAR columns) to hold all values from the input file and to ensure the import can finish without errors.</p> <p>The parameter defines the maximum length for certain columns using the following format: <code>-maxLength='firstname=30,lastname=20'</code> Where <code>firstname</code> and <code>lastname</code> are columns from the target table. The above example will limit the values for the column <code>firstname</code> to 30 characters and the values for the column <code>lastname</code> to 20 characters. If a non-character column is specified this is ignored. Note that you <b>have</b> quote the parameter's value in order to be able to use the "embedded" equals sign.</p>
<code>-booleanToNumber</code>	<p>Possible values: <code>true</code>, <code>false</code></p> <p>When exporting data from a DBMS that supports the BOOLEAN datatype, the export file will contain the literals "true" or "false" for the value of the boolean columns. When importing this file into a DBMS that does not support the BOOLEAN datatype, the import would fail.</p> <p>In case you are importing the boolean column into a numeric column in the target DBMS, SQL Workbench/J will automatically convert the literal <code>true</code> to the numeric value 1 (one) and the literal <code>false</code> to the numeric value 0 (zero). If you do not want this automatic conversion, you have to specify <code>-booleanToNumber=false</code> for the import. The default values for the true/false literals can be overwritten with the <code>-literalsFalse</code> and <code>-literalsTrue</code> switches.</p>
<code>-literalsFalse</code> <code>-literalsTrue</code>	<p>When dealing with boolean values in the input file, these two switches define the literals that represent the value <code>false</code> and the value <code>true</code> when parsing the input data.</p> <p>The value to these switches is a comma separated list of literals that should be treated as the specified value, e.g.: <code>-literalsFalse='false,0'</code> - <code>-literalsTrue='true,1'</code> will define the most commonly used values for true/false.</p> <p>Please note:</p> <ul style="list-style-type: none"> <li>• The definition of the literals is case sensitive!</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>You always have to specify both switches, otherwise the definition will be ignored</li> </ul>
-constantValues	<p>With this parameter you can supply constant values for one or more columns that will be used when inserting new rows into the database.</p> <p>The constant values will only be used when inserting rows (e.g. using <code>-mode=insert</code>)</p> <p>The format of the values is -  <code>constantValues="column1=value1,column2=value2"</code>.  The parameter can be repeated multiple times, to make quoting easier: <code>-constantValues="column1=value1" -constantValues="column2=value2"</code> The values will be converted by the same rules as the input values from the input file. If the value for a character column is enclosed in single quotes, these will be removed from the value before sending it to the database. To include single quotes at the start or end of the input value you need to use two single quotes, e.g. <code>-constantValues="name=' 'Quoted' ',title='with space'"</code> For the field name the value 'Quoted' will be sent to the database. for the field title the value with space will be sent to the database.</p> <p>To specify a function call to be executed, enclose the function call in <code>\${...}</code>, e.g. <code>\${mysequence.nextval}</code> or <code>\${myfunc()}</code>. The supplied function will be put into the VALUES part of the INSERT statement without further checking (after removing the <code>\${</code> and <code>}</code> characters, of course). So make sure that the syntax is valid for your DBMS. If you do need to store a literal like <code>\${some.value}</code> into the database, you need to quote it: <code>-constantValues="varname='\${some.value}'"</code>.</p> <p>You can also specify a SELECT statement that retrieves information from the database based on values from the input file. This is useful when the input file contains e.g. values from a lookup table (but not the primary key from the lookup table).</p> <p>The syntax to specify a SELECT statement is similar to a function call: -  <code>constantValues="\${@{SELECT type_id FROM type_definition WHERE type_name = \$4"}</code> where \$4 references the fourth column from the input file. The first column is \$1 (not \$0).</p> <p>The parameter for the SELECT statement do not need to be quoted as internally a prepared statement is used. However the values in the input file must be convertible by the JDBC driver.</p> <p>Please refer to the examples for more details on the usage.</p>
-insertSQL	<p>Define the statement to be used for inserting rows.</p> <p>This can be used to use hints or customize the generated INSERT statement. The parameter may only contain the INSERT INTO part of the statement (i.e. INSERT INTO is the default if nothing is specified). This can be used to pass special hints to the database, e.g. to specify an append hint for Oracle:</p> <p> You have to quote the parameter value using single quotes, otherwise comments will be removed from the SQL statement!</p> <p><code>-insertSQL='INSERT /*+ append */ INTO'</code></p>
-preTableStatement - postTableStatement	<p>This parameter defines a SQL statement that should be executed before the import process starts inserting data into the target table. The name of the current table (when e.g. importing a whole directory) can be referenced using <code>\${table.name}</code>.</p>

Parameter	Description
	<p>To define a statement that should be executed after all rows have been inserted and have been committed, you can use the <code>-postTableStatement</code> parameter.</p> <p>These parameters can e.g. be used to enable identity insert for MS SQL Server:</p> <pre>-preTableStatement="set identity_insert \${table.name} on" -postTableStatement="set identity_insert \${table.name} off"</pre> <p>Errors resulting from executing these statements will be ignored. If you want to abort the import in that case you can specify <code>-ignorePrePostErrors=false</code> and <code>-continueOnError=false</code>.</p>
<code>-ignorePrePostErrors=false</code>	Controls handling of errors for the <code>-preTableStatement</code> and <code>-postTableStatement</code> parameters. If this is set to false, errors resulting from executing the supplied parameters are ignored. If set to true (default) then error handling depends on the parameter <code>-continueOnError</code> .
<code>-showProgress</code>	<p>Valid values: true, false, &lt;numeric value&gt;</p> <p>Control the update frequency in the statusbar (when running in GUI mode). The default is every 10th row is reported. To disable the display of the progress specify a value of 0 (zero) or the value false. true will set the progress interval to 1 (one).</p>

## 12.2. Parameters for the type TEXT

Parameter	Description
<code>-fileColumns</code>	<p>A comma separated list of the table columns in the import file Each column from the file should be listed with the appropriate column name from the target table. This parameter also defines the order in which those columns appear in the file. If the file does not contain a header line or the header line does not contain the names of the columns in the database (or has different names), this parameter has to be supplied. If a column from the input file has no match in the target table, then it should be specified with the name <code>\$wb_skip\$</code>. You can also specify the <code>\$wb_skip\$</code> flag for columns which are present but that you want to exclude from the import.</p> <p>This parameter is ignored when the <code>-sourceDir</code> parameter is used.</p>
<code>-importColumns</code>	<p>Defines the columns that should be imported. If all columns from the input file should be imported (the default), then this parameter can be omitted. If only certain columns should be imported then the list of columns can be specified here. The column names should match the names provided with the <code>-filecolumns</code> switch. The same result can be achieved by providing the columns that should be excluded as <code>\$wb_skip\$</code> columns in the <code>-filecolumns</code> switch. Which one you choose is mainly a matter of taste. Listing all columns and excluding some using <code>-importcolumns</code> might be more readable because the structure of the file is still "visible" in the <code>-filecolumns</code> switch.</p> <p>This parameter is ignored when the <code>-sourcedir</code> parameter is used.</p>
<code>-delimiter</code>	<p>Define the character which separates columns in one line. Records are always separated by newlines (either CR/LF or a single a LF character) unless <code>-multiline=true</code> is specified</p> <p>Default value: <code>\t</code> (a tab character)</p>

Parameter	Description
-columnWidths	<p>To import files that do not have a delimiter but a fixed width for each column, this parameter defines the width of each column in the input file. The value for this parameter is a comma separated list, where each element defines the width for a single column. If this parameter is given, the <code>-delimiter</code> parameter is ignored.</p> <p>e.g.: <code>-columnWidths='name=10,lastname=20,street=50,flag=1'</code></p> <p>Note that the whole list must be enclosed in quotes as the parameter value contains the equal sign.</p> <p>If you want to import only certain columns you have to use <code>-fileColumns</code> and <code>-importColumns</code> to select the columns to import. You cannot use <code>\$wb_skip\$</code> in the <code>-fileColumns</code> parameter with a fixed column width import.</p>
-dateFormat	The <a href="#">format</a> for date columns.
-timestampFormat	The <a href="#">format</a> for datetime (or timestamp) columns in the input file.
-quoteChar	The character which was used to quote values where the delimiter is contained. This parameter has no default value. Thus if this is not specified, no quote checking will take place. If you use <code>-multiLine=true</code> you <b>have</b> to specify a quote character in order for this to work properly.
-quoteAlways	<p>Possible values: <code>true</code>, <code>false</code></p> <p>WbImport will always handled quoted values correctly, if a quote character is defined through <code>-quoteChar</code>.</p> <p>Using <code>-quoteAlways=true</code> enables the distinction between NULL values and empty strings in the import file, but only if <code>-quoteAlways=true</code> has also been used when running <a href="#">WbExport</a>. Remember to also use <code>-emptyStringIsNull=false</code>, as by default empty string values are treated as NULLs</p>
-quoteCharEscaping	<p>Possible values: <code>none</code>, <code>escape</code>, <code>duplicate</code></p> <p>Defines how quote characters that appear in the actual data are stored in the input file.</p> <p>You have to define a quote character in order for this option to have an effect. The character defined with the <code>-quoteChar</code> switch will then be imported according to the setting defined by this switch.</p> <p>If <code>escape</code> is specified, it is expected that a quote that is part of the data is preceded with a backslash, e.g. the input value here is a <code>\"</code> quote character will be imported as here is a <code>"</code> quote character</p> <p>If <code>duplicate</code> is specified, it is expected that the quote character is duplicated in the input data. This is similar to the handling of single quotes in SQL literals. The input value here is a <code>" "</code> quote character will be imported as here is a <code>"</code> quote character</p>
-multiLine	<p>Possible values: <code>true</code>, <code>false</code></p> <p>Enable support for records spanning more than one line in the input file. These records have to be quoted, otherwise they will not be recognized.</p> <p>If you create your exports with the <a href="#">WbExport</a> command, it is recommended to encode special characters using the <code>-escapetext</code> switch rather than using multi-line records.</p>

Parameter	Description
	The default value for this parameter can be controlled in the <a href="#">settings file</a> and it will be displayed if you run WbImport without any parameters.
-decimal	The decimal symbol to be used for numbers. The default is a dot
-header	<p>Possible values: true, false</p> <p>If set to true, indicates that the file contains a header line with the column names for the target table. This will also ignore the data from the first line of the file. If the column names to be imported are defined using the <code>-filecolumns</code> or the <code>-importcolumns</code> switch, this parameter has to be set to true nevertheless, otherwise the first row would be treated as a regular data row.</p> <p>This parameter is always set to true when the <code>-sourcedir</code> parameter is used.</p> <p>The default value for this option can be changed in the <a href="#">settings file</a> and it will be displayed if you run WbImport without any parameters. It defaults to true</p>
-decode	<p>Possible values: true, false</p> <p>This controls the decoding of escaped characters. If the export file was e.g. written with <a href="#">escaping enabled</a> then you need to set <code>-decode=true</code> in order to interpret string sequences like <code>\t</code>, <code>\n</code> or escaped Unicode characters properly. This is not enabled by default because applying the necessary checks has an impact on the performance.</p>
-columnFilter	<p>This defines a filter on column level that selects only certain rows from the input file to be sent to the database. The filter has to be defined as <code>column1="regex", column2="regex"</code>. Only Rows matching all of the supplied regular expressions will be included by the import.</p> <p>This parameter is ignored when the <code>-sourcedir</code> parameter is used.</p>
-lineFilter	<p>This defines a filter on the level of the whole input row (rather than for each column individually). Only rows matching this regular expression will be included in the import.</p> <p>The complete content of the row from the input file will be used to check the regular expression. When defining the expression, remember that the (column) delimiter will be part of the input string of the expression.</p>
-emptyStringIsNull	<p>Possible values: true, false</p> <p>Controls whether input values for character type columns with a length of zero are treated as NULL (value true) or as an empty string.</p> <p>The default value for this parameter is true</p> <p>Note that, input values for non character columns (such as numbers or date columns) that are empty or consist only of whitespace will always be treated as NULL.</p>
-trimValues	<p>Possible values: true, false</p> <p>Controls whether leading and trailing whitespace are removed from the input values before they are stored in the database. When used in combination with <code>-emptyStringIsNull=true</code> this means that a column value that contains only whitespace will be stored as NULL in the database.</p> <p>The default value for this parameter can be controlled in the <a href="#">settings file</a> and it will be displayed if you run WbImport without any parameters.</p>

Parameter	Description
	Note that, input values for non character columns (such as numbers or date columns) are always trimmed before converting them to their target datatype.
-blobIsFilename	<p>Possible values: true, false</p> <p>This is a deprecated parameter. Please use -blobType instead.</p> <p>When exporting tables that have BLOB columns using <a href="#">WbExport</a> into text files, each BLOB will be written into a separate file. The actual column data of the text file will contain the file name of the external file. When importing text files that do not reference external files into tables with BLOB columns setting this parameter to false, will send the content of the BLOB column "as is" to the DBMS. This will of course only work if the JDBC driver can handle the data that in the BLOB columns of the text file. The default for this parameter is true</p> <p>This parameter is ignored, if -blobType is also specified.</p>
-blobType	<p>Possible values: file, ansi, base64</p> <p>Specifies how BLOB data is stored in the input file. If file is specified, it is assumed that the column value contains a filename that in turn contains the real blob data. This is the default format when using <a href="#">WbExport</a>.</p> <p>For the other two type, WbImport assumes that the blob data is stored as encoded character data in the column.</p> <p>If this parameter is specified, -blobIsFilename is ignored.</p>
-clobIsFilename	<p>Possible values: true, false</p> <p>When exporting tables that have CLOB columns using <a href="#">WbExport</a> and the parameter -clobAsFile=true the generated text file will not contain the actual CLOB contents, but the a filename indicating the file in which the CLOB content is stored. In this case -clobIsFilename=true has to be specified in order to read the CLOB contents from the external files. The CLOB files will be read using the encoding specified with the -encoding parameter.</p>

## 12.3. Text Import Examples

### 12.3.1. Importing date columns

```
WbImport -file=c:/temp/contacts.txt
        -table=person
        -filecolumns=lastname,firstname,birthday
        -dateformat="yyyy-MM-dd";
```

This imports a file with three columns into a table named person. The first column in the file is lastname, the second column is firstname and the third column is birthday. Values in date columns are formatted as yyyy-MM-dd

A special timestamp format millis is available to identify times represented in milliseconds (since January 1, 1970, 00:00:00 GMT).

### 12.3.2. Excluding input columns from the import

```
WbImport -file=c:/temp/contacts.txt
```

```
-table=person
-filecolumns=lastname,firstname,$wb_skip$,birthday
-dateformat="yyyy-MM-dd";
```

This will import a file with four columns. The third column in the file does not have a corresponding column in the table `person` so its specified as `$wb_skip$` and will not be imported.

```
WbImport -file=c:/temp/contacts.txt
-table=person
-filecolumns=lastname,firstname,phone,birthday
-importcolumns=lastname,firstname;
```

This will import a file with four columns where all columns exist in the target table. Only `lastname` and `firstname` will be imported. The same effect could be achieved by specifying `$wb_skip$` for the last two columns and leaving out the `-importcolumns` switch. Using `-importcolumns` is a bit more readable because you can still see the structure of the input file. The version with `$wb_skip$` is mandatory if the input file contains columns that do not exist in the target table.

### 12.3.3. Filtering rows during import

If you want to import certain rows from the input file, you can use regular expressions:

```
WbImport -file=c:/temp/contacts.txt
-table=person
-filecolumns=lastname,firstname,birthday
-columnfilter=lastname="^Bee.*",firstname="^Za.*"
-dateformat="yyyy-MM-dd";
```

The above statement will import only rows where the column `lastname` contains values that start with `Bee` and the column `firstname` contains values that start with `Za`. So `Zaphod Beeblebrox` would be imported, `Arthur Beeblebrox` would not be imported.

If you want to learn more about regular expressions, please have a look at <http://www.regular-expressions.info/>

If you want to limit the rows that are updated but cannot filter them from the input file using `-columnfilter` or `-linefilter`, use the `-updatewhere` parameter:

```
WbImport -file=c:/temp/contacts.txt
-table=person
-filecolumns=id,lastname,firstname,birthday
-keycolumns=id
-mode=update
-updatewhere="source <> 'manual' "
```

This will update the table `PERSON`. The generated `UPDATE` statement would normally be: `UPDATE person SET lastname=?, firstname=?, birthday=? WHERE id=?`. The table contains entries that are maintained manually (identified by the value `'manual'` in the column `source`) and should not be updated by SQL Workbench/J. By specifying the `-updatewhere` parameter, the above `UPDATE` statement will be extended to `WHERE id=? AND (source <> 'manual')`. Thus skipping records that are flagged as `manual` even if they are contained in the input file.

### 12.3.4. Importing several files

```
WbImport -sourceDir=c:/data/backup
-extension=txt
-header=true
```

This will import all files with the extension `txt` located in the directory `c:/data/backup` into the database. This assumes that each filename indicates the name of the target table.

```
WbImport -sourceDir=c:/data/backup
        -extension=txt
        -table=person
        -header=true
```

This will import all files with the extension `txt` located in the directory `c:/data/backup` into the table `person` regardless of the name of the input file. In this mode, the parameter `-deleteTarget` will be ignored.

### 12.3.5. Populating columns from the database

When your input file does not contain the actual values to be stored in the target table, but e.g. lookup values, you can specify a `SELECT` statement to retrieve the necessary primary key of the lookup table.

Consider the following tables:

```
contact (contact_id, first_name, last_name, type_id)
contact_type (type_id, type_name)
```

The table `contact_type` contains: (1, 'business'), (2, 'private'), (3, 'other').

Your input file only contains `contact_id`, `first_name`, `last_name`, `type_name`. Where `type_name` references an entry from the `contact_type` table.

To import this file, the following statement can be used:

```
WbImport
  -file=contacts.txt
  -type=text
  -header=true
  -table=contact
  -importColumns=contact_id, first_name, last_name
  -constantValues="type_id=${SELECT type_id FROM contact_type WHERE type_name = $4}"
```

For every row from the input file, SQL Workbench/J will run the specified `SELECT` statement. The value of the first column of the first row that is returned by the `SELECT`, will then be used to populate the `type_id` column. The `SELECT` statement will use the value of the third column of the row that is currently being inserted as the value for the `WHERE` condition.

You must use the `-importColumns` parameter as well to make sure the `type_name` column is not processed! As an alternative you can also use `-fileColumns=contact_id, first_name, last_name, $wb_skip$` instead of `-importColumns`.

The "placeholders" with the column index must not be quoted (e.g. '\$1' for a character column will not work)!

If the column `contact_id` should be populated by a sequence, the above statement can be extended to include a function call to retrieve the sequence value (PostgreSQL syntax:)

```
WbImport
  -file=contacts.txt
  -type=text
  -header=true
  -table=contact
  -importColumns=first_name, last_name
  -constantValues="id=${nextval('contact_id_seq'::regclass)}"
```

```
-constantValues="type_id=${SELECT type_id FROM contact_type WHERE type_name = $4}"
```

As the ID column is now populated through a constant expression, it may not appear in the `-importColumns` list. Again you could alternatively use `-fileColumns=$wb_skip$, first_name, last_name, $wb_skip$` to make sure the columns that are populated through the `-constantValue` parameter are not taken from the input file.

## 12.4. Parameters for the type XML

The XML import only works with files generated by the [WbExport](#) command.

Parameter	Description
-verboseXML	<p>Possible values: true, false</p> <p>If the XML was generated with <code>-verboseXML=false</code> then this needs to be specified also when importing the file. Beginning with build 78, the SQL Workbench/J writes the information about the used tags into the meta information. So it is no longer necessary to specify whether <code>-verboseXML</code> was true when creating the XML file.</p>
-sourceDir	<p>Specify a directory which contains the XML files. All files in that directory ending with ".xml" (lowercase!) will be processed. The table into which the data is imported is read from the XML file, also the columns to be imported. The parameters <code>-keycolumns</code>, <code>-table</code> and <code>-file</code> are ignored if this parameter is specified. If XML files are used that are generated with a version prior to build 78, then all files need to use either the long or short tag format and the <code>-verboseXML=false</code> parameter has to be specified if the short format was used.</p> <p>When importing several files at once, the files will be imported into the tables specified in the XML files. You cannot specify a different table (apart from editing the XML file before starting the import).</p>
-importColumns	Defines the columns that should be imported. If all columns from the input file should be imported (the default), then this parameter can be omitted. When specified, the columns have to match the column names available in the XML file.
-createTarget	If this parameter is set to <code>true</code> the target table will be created, if it doesn't exist. Valid values are <code>true</code> or <code>false</code> .

## 12.5. Update mode

The `-mode` parameter controls the way the data is sent to the database. The default is `INSERT`. SQL Workbench/J will generate an `INSERT` statement for each record. If the `INSERT` fails no further processing takes place for that record.

If `-mode` is set to `UPDATE`, SQL Workbench/J will generate an `UPDATE` statement for each row. In order for this to work, the table needs to have a primary key defined, and all columns of the primary key need to be present in the import file. Otherwise the generated `UPDATE` statement will modify rows that should not be modified. This can be used to update existing data in the database based on the data from the export file.

To either update or insert data into the table, both keywords can be specified for the `-mode` parameter. The order in which they appear as the parameter value, defines the order in which the respective statements are sent to the database. If the first statement fails, the second will be executed. For `-mode=insert, update` to work properly a primary or unique key has to be defined on the table. SQL Workbench/J will catch any exception (=error) when inserting a record, then it will try updating the record, based on the specified `keycolumns`. The `-mode=update, insert` works the other way. First SQL Workbench/J will try to update the record based on the primary keys. If the DBMS signals that no rows have been updated, it is assumed that the row does not exist and the record will be inserted into the table. This mode is recommended when no primary or unique key is defined on the table, and an `INSERT` would always succeed.

The `keycolumns` defined with the `-keycolumns` parameter don't have to match the real primary key, but they should identify one row uniquely.

You cannot use the update mode, if the tables in question **only** consist of key columns (or if only key columns are specified). The values from the source are used to build up the `WHERE` clause for the `UPDATE` statement.

If you specify a combined mode (e.g.: `update, insert`) and one of the tables involved consists only of key columns, the import will revert to `insert` mode. In this case database errors during an `INSERT` are not considered as real errors and are silently ignored.

For maximum performance, choose the update strategy that will result in a successful first statement more often. As a rule of thumb:

- Use `-mode=insert, update`, if you expect more rows to be inserted then updated.
- Use `-mode=update, insert`, if you expect more rows to be updated then inserted.

To use `insert/update` or `update/insert` with PostgreSQL, make sure you have [enabled savepoints](#) for the import (which is enabled by default).

## 13. Copy data across databases

The `WbCopy` is essentially the command line version of the the [DataPumper](#). For a more detailed explanation of the copy process, please refer to that section. It basically chains a `WbExport` and a `WbImport` statement without the need of an intermediate data file. The `WbCopy` command requires that a connection to the source and target database can be made at the same time.

### 13.1. General parameters for the `WbCopy` command.

Parameter	Description
<code>-sourceProfile</code>	<p>The name of the connection profile to use as the source connection. If <code>-sourceprofile</code> is not specified, the current connection is used as the source.</p> <p>If the profile name contains spaces or dashes, it has to be quoted.</p>
<code>-sourceGroup</code>	<p>If the name of your source profile is not unique across all profiles, you will need to specify the group in which the profile is located with this parameter.</p> <p>If the group name contains spaces or dashes, it has to be quoted.</p>
<code>-targetProfile</code>	<p>The name of the connection profile to use as the target connection. If <code>-targetprofile</code> is not specified, the current connection is used as the target.</p> <p>If the profile name contains spaces or dashes, it has to be quoted.</p>
<code>-targetGroup</code>	<p>If the name of your target profile is not unique across all profiles, you will need to specify the group in which the profile is located with this parameter.</p> <p>If the group name contains spaces or dashes, it has to be quoted.</p>
<code>-commitEvery</code>	<p>The number of rows after which a commit is sent to the target database. This parameter is ignored if JDBC batching (<code>-batchSize</code>) is used.</p>
<code>-deleteTarget</code>	<p>Possible values: <code>true</code>, <code>false</code></p> <p>If this parameter is set to <code>true</code>, all rows are deleted from the target table before copying the data.</p>
<code>-mode</code>	<p>Defines how the data should be sent to the database. Possible values are <code>INSERT</code>, <code>UPDATE</code>, <code>'INSERT , UPDATE'</code> and <code>'UPDATE , INSERT'</code>. Please refer to the description of the <a href="#">WbImport</a> command for details on.</p>
<code>-syncDelete</code>	<p>If this option is enabled <code>-syncDelete=true</code>, SQL Workbench/J will check each row from the target table if it's present in the source table. Rows in the target table that are not present in the source will be deleted. As this is implemented by checking each row individually in the source table, this can take some time for large tables. This option requires that each table in question has a primary key defined.</p> <p>Combined with an <code>UPDATE , INSERT</code> or <code>UPDATE , INSERT</code> mode this creates an exact copy of the source table.</p> <p>If more than one table is copied, the delete process is started after all inserts and updates have been processed. It is recommended to use the <code>-checkDependencies</code> parameter to make sure the deletes are processed in the correct order (which is most probably already needed to process inserts correctly).</p> <p>To only generate the SQL statements that would synchronize two databases, you can use the command <a href="#">WbDataDiff</a></p>

Parameter	Description
-keyColumns	Defines the key columns for the target table. This parameter is only necessary if import is running in UPDATE mode. It is ignored when specifying more than one table with the <code>-sourceTable</code> argument. In that case each table must have a primary key.
-batchSize	<p>Enable the use of the JDBC batch update feature, by setting the size of the batch queue. Any value greater than 1 will enable batch mode. If the JDBC driver supports this, the INSERT (or UPDATE) performance can be increased.</p> <p>This parameter will be ignored if the driver does not support batch updates or if the mode is not UPDATE or INSERT (i.e. if <code>-mode=update, insert</code> or <code>-mode=insert, update</code> is used).</p>
-commitBatch	<p>Valid values: <code>true, false</code></p> <p>When using the <code>-batchSize</code> parameter, the <code>-commitEvery</code> is ignored (as not all JDBC drivers support a COMMIT inside a JDBC batch operation. When using <code>-commitBatch=true</code> SQL Workbench/J will send a COMMIT to the database server after each JDBC batch is sent to the server.</p>
-continueOnError	<p>Defines the behaviour if an error occurs in one of the statements. If this is set to <code>true</code> the copy process will continue even if one statement fails. If set to <code>false</code> the copy process will be halted on the first error. The default value is <code>false</code>.</p> <p>With PostgreSQL <code>continueOnError</code> will only work, if the use of savepoints is enabled using <code>-useSavepoint=true</code>.</p>
-useSavepoint	<p>Possible values: <code>true, false</code></p> <p>Controls if SQL Workbench/J guards every insert or update statement with a savepoint to recover from individual error during import, when <code>continueOnError</code> is set to <code>true</code>.</p> <p>Using a savepoint for each DML statement can drastically reduce the performance of the import.</p>
-showProgress	<p>Valid values: <code>true, false, &lt;numeric value&gt;</code></p> <p>Control the update frequency in the statusbar (when running in GUI mode). The default is every 10th row is reported. To disable the display of the progress specify a value of 0 (zero) or the value <code>false</code>. <code>true</code> will set the progress interval to 1 (one).</p>

## 13.2. Copying data from one or more tables

Parameter	Description
-sourceTable	The name of the table(s) to be copied. You can either specify a list of tables: <code>-sourceTable=table1, table2</code> . Or select the tables using a wildcard: <code>-sourceTable=*</code> will copy all tables accessible to the user. If more than one table is specified using this parameter, the <code>-targetTable</code> parameter is ignored.
-checkDependencies	When copying more than one file into tables with foreign key constraints, this switch can be used to import the files in the correct order (child tables first). When <code>-checkDependencies=true</code> is passed, SQL Workbench/J will check the foreign key dependencies for the tables specified with <code>-sourceTable</code>
-sourceWhere	A WHERE condition that is applied to the source table.
-targetTable	The name of the table into which the data should be written. This parameter is ignored if more than one table is copied.

Parameter	Description
-createTarget	<p>If this parameter is set to <code>true</code> the target table will be created, if it doesn't exist. Valid values are <code>true</code> or <code>false</code>.</p> <p>When using this option with different source and target DBMS, the information about the datatypes to be used in the target database are retrieved from the JDBC driver. In some cases this information might not be accurate or complete. You can enhance the information from the driver by configuring your own mappings in <code>workbench.settings</code>. Please see the section <a href="#">Customizing data type mapping</a> for details.</p>
-tableType	<p>When <code>-createTarget</code> is set to <code>true</code>, this parameter can be used to control the SQL statement that is generated to create the target table. This is useful if the target table should e.g. be a temporary table</p> <p>When using the auto-completion for this parameter, all defined "create types" that are configured in <code>workbench.settings</code> (or are part of the default settings) are displayed together with the name of the DBMS they are used for. The list is <b>not</b> limited to definitions for the target database! The specified type must nonetheless match a type defined for the target connection. If you specify a type that does not exist, the default <code>CREATE TABLE</code> will be used.</p> <p>For details on how to configure a <code>CREATE TABLE</code> template for this parameter, please refer to the chapter <a href="#">Settings related to SQL statement generation</a></p>
-skipTargetCheck	<p>Normally WbCopy will check if the specified target table does exist. However, some JDBC drivers do not always return all table information correctly (e.g. temporary tables). If you know that the target table exists, the parameter <code>-skipTargetCheck=true</code> can be used to tell WbCopy, that the (column) definition of the source table should be assumed for the target table and not further test for the target table will be done.</p>
-dropTarget	<p>If this parameter is set to <code>true</code> the target table will be dropped before it is created.</p>
-columns	<p>Defines the columns to be copied. If this parameter is not specified, then all matching columns are copied from source to target. Matching is done on name <b>and</b> data type. You can either specify a list of columns or a column mapping.</p> <p>When supplying a list of columns, the data from each column in the source table will be copied into the corresponding column (i.e. one with the same name) in the target table. If <code>-createTarget=true</code> is specified then this list also defines the columns of the target table to be created. The names have to be separated by comma: <code>-columns=firstname, lastname, zipcode</code></p> <p>A column mapping defines which column from the source table maps to which column of the target table (if the column names do not match) If <code>-createtable=true</code> then the target table will be created from the specified target names: <code>-columns=firstname/surname, lastname/name, zipcode/zip</code> Will copy the column <code>firstname</code> from the source table to a column named <code>surname</code> in the target table, and so on.</p> <p>This parameter is ignored if more than one table is copied.</p> <p>When using a <i>SQL query</i> as the data source a <i>mapping</i> cannot be specified. Please check <a href="#">Copying data based on a SQL query</a> for details.</p>
-preTableStatement - postTableStatement	<p>This parameter defines a SQL statement that should be executed before the import process starts inserting data into the target table. The name of the current table (when e.g. importing a whole directory) can be referenced using <code>\${table.name}</code>.</p> <p>To define a statement that should be executed after all rows have been inserted and have been committed, you can use the <code>-postTableStatement</code> parameter.</p>

Parameter	Description
	<p>These parameters can e.g. be used to enable identity insert for MS SQL Server:</p> <pre>-preTableStatement="set identity_insert \${table.name} on" -postTableStatement="set identity_insert \${table.name} off"</pre> <p>Errors resulting from executing these statements will be ignored. If you want to abort the import in that case you can specify <code>-ignorePrePostErrors=false</code> and <code>-continueOnError=false</code>.</p>
<code>-ignorePrePostErrors=false</code>	Controls handling of errors for the <code>-preTableStatement</code> and <code>-postTableStatement</code> parameters. If this is set to false, errors resulting from executing the supplied parameters are ignored. If set to true (default) then error handling depends on the parameter <code>-continueOnError</code> .

### 13.3. Copying data based on a SQL query

Parameter	Description
<code>-sourceQuery</code>	The SQL query to be used as the source data (instead of a table).
<code>-columns</code>	<p>The <i>list</i> of columns from the target table, in the order in which they appear in the source query.</p> <p>If the column names in the query match the column names in the target table, this parameter is not necessary.</p> <p>If you do specify this parameter, note that this is <b>not</b> a column mapping. It only lists the columns in the correct order .</p>

### 13.4. Update mode

The `WbCopy` command understands the same update mode parameter as the `WbImport` command. For a discussion on the different update modes, please refer to the [WbImport](#) command.

### 13.5. Synchronizing tables

Using `-mode=update,insert` ensures that all rows that are present in the source table do exist in the target table and that all values for non-key columns are identical.

When you need to keep two tables completely in sync, rows that are present in the target table that do not exist in the source table need to be deleted. This is what the parameter `-syncDelete` is for. If this is enabled (`-syncDelete=true`) then SQL Workbench/J will check every row from the target table if it is present in the source table. This check is based on the primary keys of the target table and assumes that the source table has the same primary key.

Testing if each row in the target table exists in the source table is a substantial overhead, so you should enable this option only when really needed. `DELETES` in the target table are batched according to the `-batchSize` setting of the `WbCopy` command. To increase performance, you should enable batching for the whole process.

Internally the rows from the source table are checked in chunks, which means that SQL Workbench/J will generate a `SELECT` statement that contains a `WHERE` condition for each row retrieved from the target table. The default chunk size is relatively small to avoid problems with large SQL statements. This approach was taken to minimize the number of statements sent to the server.

The [automatic fallback](#) [87] from update, insert or insert, update mode to insert mode applies for synchronizing tables using WbCopy as well.

## 13.6. Examples

### 13.6.1. Copy one table to another where all column names match

```
WbCopy -sourceProfile=ProfileA
       -targetProfile=ProfileB
       -sourceTable=the_table
       -targetTable=the_other_table;
```

### 13.6.2. Synchronize the tables between two databases

This example will copy the data from the tables in the source database to the corresponding tables in the target database. Rows that are not available in the source tables are deleted from the target tables.

```
WbCopy -sourceProfile=ProfileA
       -targetProfile=ProfileB
       -sourceTable=*
       -mode=update,insert
       -syncDelete=true;
```

### 13.6.3. Copy only selected rows

```
WbCopy -sourceProfile=ProfileA
       -targetProfile=ProfileB
       -sourceTable=the_table
       -sourceWhere="lastname LIKE 'D%'"
       -targetTable=the_other_table;
```

This example will run the statement `SELECT * FROM the_table WHERE lastname like 'D%'` and copy all corresponding columns to the target table `the_other_table`.

### 13.6.4. Copy data between tables with different columns

This example copies only selected columns from the source table. The column names in the two tables do not match and a column mapping is defined. Before the copy is started all rows are deleted from the target table.

```
WbCopy -sourceProfile=ProfileA
       -targetProfile=ProfileB
       -sourceTable=person
       -targetTable=contacts
       -deleteTarget=true
       -columns=firstname/surname, lastname/name, birthday/dob;
```

### 13.6.5. Copy data based on a SQL query

When using a query as the source for the WbCopy command, the column mapping is specified by simply supplying the order of the target columns as they appear in the `SELECT` statement.

```
WbCopy -sourceProfile=ProfileA
```

```
-targetProfile=ProfileB
-sourceQuery="SELECT firstname, lastname, birthday FROM person"
-targetTable=contacts
-deleteTarget=true
-columns=surname, name, dob;
```

This copies the data based on the SELECT statement into the table CONTACTS of the target database. The `-columns` parameter defines that the first column of the SELECT (firstname) is copied into the target column with the name surname, the second result column (lastname) is copied into the target column name and the last source column (birthday) is copied into the target column dob.

This example could also be written as:

```
WbCopy -sourceProfile=ProfileA
       -targetProfile=ProfileB
       -sourceQuery="SELECT firstname as surname, lastname as name, birthday as dob FROM p
       -targetTable=contacts
       -deleteTarget=true
```

## 14. Other SQL Workbench/J specific commands

In addition to the [WbExport](#), [WbImport](#) and [WbCopy](#) commands, SQL Workbench/J implements a set of additional SQL commands that are not part of the SQL standard. These commands can be used like any other SQL command (such as UPDATE inside SQL Workbench/J, i.e. inside the editor or as part of a SQL script that is run through SQL Workbench/J in [batch mode](#)).

As those commands are implemented by SQL Workbench/J you will not be able to use them when running your SQL scripts using a different client program (e.g. `psql`, `SQL*Plus` or `phpmyadmin`).

### 14.1. Create a report of the database objects - WbSchemaReport

Creates an XML report of selected tables. This report could be used to generate an HTML documentation of the database (e.g. using the [XSLT](#) command). This report can also be generated from within the [Database Object Explorer](#)

The resulting XML file can be transformed into a HTML documentation of your database schema. Sample stylesheets can be downloaded from <http://www.sql-workbench.net/xstl.html>. If you have XSLT stylesheets that you would like to share, please send them to [<support@sql-workbench.net>](mailto:support@sql-workbench.net).

To see table and column comments with an Oracle database, you need to [enable remarks reporting](#) for the JDBC driver, otherwise the driver will not return comments.

The command supports the following parameters:

Parameter	Description
-file	The filename of the output file.
-tables	A (comma separated) list of tables to report. Default is all tables. If this parameter is specified -schemas is ignored. If you want to generate the report on tables from different users/schemas you have to use fully qualified names in the list (e.g. -tables=MY_USER.TABLE1, OTHER_USER.TABLE2) You can also specify wildcards in the table name: -table=CONTRACT_% will create an XML report for all tables that start with CONTRACT_.
-excludeTableNames	A (comma separated) list of tables to exclude from reporting. This is only used if -tables is also specified. To create a report on all tables, but exclude those that start with 'DEV', use -tables=* -excludeTableNames=DEV*
-schemas	A (comma separated) list of schemas to generate the report from. For each user/schema all tables are included in the report. e.g. -schemas=MY_USER, OTHER_USER would generate a report for all tables in the schemas MY_USER and OTHER_USER.
-includeTables	Control the output of table information for the report. The default is true. Valid values are true, false.
-includeTableGrants	If tables are included in the output, the grants for each table can also be included with this parameter. The default value is false.
-includeProcedures	Control the output of stored procedure information for the report. The default is false. Valid values are true, false.
-includeTriggers	This parameter controls if table triggers are added to the output. The default value is true.
-includeSequences	Control the output of sequence information for the report. The default is false. Valid values are true, false.
-reportTitle	Defines the title for the generated XML file. The specified title is written into the tag <report-title> and can be used when transforming the XML e.g. into a HTML file.
-stylesheet	Apply a XSLT transformation to the generated XML file.

Parameter	Description
-xsltOutput	The name of the generated output file when applying the XSLT transformation.

## 14.2. Compare two database schemas - WbSchemaDiff

WbSchemaDiff analyzes two schemas (or a list of tables) and outputs the differences between those schemas as an XML file. The XML file describes the changes that need to be applied to the target schema to have the same structure as the reference schema, e.g. modify column definitions, remove or add tables, remove or add indexes.

The output is intended to be transformed using XSLT (e.g. with the [XSLT Command](#)). Sample XSLT transformations can be found on the [SQL Workbench/J homepage](#)

The command supports the following parameters:

Parameter	Description
-referenceProfile	The name of the connection profile for the reference connection. If this is not specified, then the current connection is used.
-referenceGroup	If the name of your reference profile is not unique across all profiles, you will need to specify the group in which the profile is located with this parameter.
-targetProfile	The name of the connection profile for the target connection (the one that needs to be migrated). If this is not specified, then the current connection is used.  If you use the current connection for reference and target, then you should prefix the table names with schema/user or use the <code>-referenceschema</code> and <code>-targetschema</code> parameters.
-targetGroup	If the name of your target profile is not unique across all profiles, you will need to specify the group in which the profile is located with this parameter.
-file	The filename of the output file. If this is not supplied the output will be written to the message area
-referenceTables	A (comma separated) list of tables that are the reference tables, to be checked.
-targetTables	A (comma separated) list of tables in the target connection to be compared to the source tables. The tables are "matched" by their position in the list. The first table in the <code>-referenceTables</code> parameter is compared to the first table in the <code>-targetTables</code> parameter, and so on. Using this parameter you can compare tables that do not have the same name.  If you omit this parameter, then all tables from the target connection with the same names as those listed in <code>-referenceTables</code> are compared.  If you omit both parameters, then all tables that the user can access are retrieved from the source connection and compared to the tables with the same name in the target connection.
-referenceSchema	Compare all tables from the specified schema (user)
-targetSchema	A schema in the target connection to be compared to the tables from the reference schema.
-encoding	The encoding to be used for the XML file. The default is UTF-8
-includePrimaryKeys	Select whether primary key constraint definitions should be compared as well. The default is <code>true</code> . Valid values are <code>true</code> or <code>false</code> .
-includeForeignKeys	Select whether foreign key constraint definitions should be compared as well. The default is <code>true</code> . Valid values are <code>true</code> or <code>false</code> .
-includeTableGrants	Select whether table grants should be compared as well. The default is <code>false</code> .

Parameter	Description
-includeTriggers	Select whether table triggers are compared as well. The default value is <code>true</code> .
-includeConstraints	Select whether table and column (check) constraints should be compared as well. SQL Workbench/J compares the constraint definition (SQL) as stored in the database.  The default is to compare table constraints ( <code>true</code> ) Valid values are <code>true</code> or <code>false</code> .
-useConstraintNames	When including check constraints this parameter controls whether constraints should be matched by name, or only by their expression. If comparing by names is enabled, the diff output will contain elements for constraint modification otherwise only drop and add entries will be available.  The default is to compare by names( <code>true</code> ) Valid values are <code>true</code> or <code>false</code> .
-includeViews	Select whether views should also be compared. When comparing views, the source as it is stored in the DBMS is compared. This comparison is case-sensitive, which means <code>SELECT * FROM foo;</code> will be reported as a difference to <code>select * from foo;</code> even if they are logically the same. A comparison across different DBMS will also not work properly!  The default is <code>true</code> Valid values are <code>true</code> or <code>false</code> .
-includeProcedures	Select whether stored procedures should also be compared. When comparing procedures the source as it is stored in the DBMS is compared. This comparison is case-sensitive. A comparison across different DBMS will also not work!  The default is <code>false</code> Valid values are <code>true</code> or <code>false</code> .
-includeIndex	Select whether indexes should be compared as well. The default is to not compare index definitions. Valid values are <code>true</code> or <code>false</code> .
-includeSequences	Select whether sequences should be compared as well. The default is to not compare sequences. Valid values are <code>true</code> , <code>false</code> .
-useJdbcTypes	Define whether to compare the DBMS specific data types, or the JDBC data type returned by the driver. When comparing tables from two different DBMS it is recommended to use <code>-useJdbcType=true</code> as this will make the comparison a bit more DBMS-independent. When comparing e.g. Oracle vs. PostgreSQL a column defined as <code>VARCHAR2(100)</code> in Oracle would be reported as being different to a <code>VARCHAR(100)</code> column in PostgreSQL which is not really true As both drivers report the column as <code>java.sql.Types.VARCHAR</code> , they would be considered as identical when using <code>-useJdbcType=true</code> .  Valid values are <code>true</code> or <code>false</code> .
-stylesheet	Apply a XSLT transformation to the generated XML file.
-xsltOutput	The name of the generated output file when applying the XSLT transformation.

### 14.3. Compare data across databases - WbDataDiff

The `WbDataDiff` command can be used to generate SQL scripts that update a target database such that the data is identical to a reference database. This is similar to the `WbSchemaDiff` but compares the actual data in the tables rather than the table structure.

For each table the command will create up to three script files, depending on the needed statements to migrate the data. One file for `UPDATE` statements, one file for `INSERT` statements and one file for `DELETE` statements (if `-includeDelete=true` is specified)

As this command needs to read every row from the reference and the target table, processing large tables can take quite some time, especially if `DELETE` statements should also be generated.

`WbDataDiff` requires that all involved tables have a primary key defined. If a table does not have a primary key, `WbDataDiff` will stop the processing.

To improve performance (a bit), the rows are retrieved in chunks from the target table by dynamically constructing a WHERE clause for the rows that were retrieved from the reference table. The chunk size can be controlled using the property `workbench.sql.sync.chunksize`. The chunk size defaults to 25. This is a conservative setting to avoid problems with long SQL statements when processing tables that have a PK with multiple columns. If you know that your primary keys consist only of a single column and the values won't be too long, you can increase the chunk size, possibly increasing the performance when generating the SQL statements. As most DBMS have a limit on the length of a single SQL statement, be careful when setting the chunksize too high. The same chunk size is applied when generating DELETE statements by the [WbCopy](#) command, when [syncDelete](#) mode is enabled.

The command supports the following parameters:

Parameter	Description
-referenceProfile	The name of the connection profile for the reference connection. If this is not specified, then the current connection is used.
-referenceGroup	If the name of your reference profile is not unique across all profiles, you will need to specify the group in which the profile is located with this parameter. If the profile's name is unique you can omit this parameter
-targetProfile	The name of the connection profile for the target connection (the one that needs to be migrated). If this is not specified, then the current connection is used.  If you use the current connection for reference and target, then you should prefix the table names with schema/user or use the <code>-referenceschema</code> and <code>-targetschema</code> parameters.
-targetGroup	If the name of your target profile is not unique across all profiles, you will need to specify the group in which the profile is located with this parameter.
-file	The filename of the main script file. The command creates two scripts per table. One script named <code>update_&lt;tablename&gt;.sql</code> that contains all needed UPDATE or INSERT statements. The second script is named <code>delete_&lt;tablename&gt;.sql</code> and will contain all DELETE statements for the target table. The main script merely calls (using <a href="#">WbInclude</a> ) the generated scripts for each table.
-referenceTables	A (comma separated) list of tables that are the reference tables, to be checked. You can specify the table with wildcards, e.g. <code>-referenceTables=P%</code> to compare all tables that start with the letter P.
-targetTables	A (comma separated) list of tables in the target connection to be compared to the source tables. The tables are "matched" by their position in the list. The first table in the <code>-referenceTables</code> parameter is compared to the first table in the <code>-targetTables</code> parameter, and so on. Using this parameter you can compare tables that do not have the same name.  If you omit this parameter, then all tables from the target connection with the same names as those listed in <code>-referenceTables</code> are compared.  If you omit both parameters, then all tables that the user can access are retrieved from the source connection and compared to the tables with the same name in the target connection.
-referenceSchema	Compare all tables from the specified schema (user)
-targetSchema	A schema in the target connection to be compared to the tables from the reference schema.
-checkDependencies	Valid values are <code>true</code> , <code>false</code> .  Sorts the generated scripts in order to respect foreign key dependencies for deleting and inserting rows.

Parameter	Description
	The default is <code>true</code> .
<code>-includeDelete</code>	Valid values are <code>true</code> , <code>false</code> .  Generates <code>DELETE</code> statements for rows that are present in the target table, but not in the reference table. The default is <code>false</code> .  The default is <code>false</code> .
<code>-type</code>	Valid values are <code>sql</code> , <code>xml</code>  Defines the type of the generated files.
<code>-encoding</code>	The encoding to be used for the SQL scripts. The default depends on your operating system. It will be displayed when you run <code>WbDataDiff</code> without any parameters. You can overwrite the platform default with the property <code>workbench.encoding</code> in the file <code>workbench.settings</code>  XML files are always stored in UTF-8
<code>-sqlDateLiterals</code>	Valid values: <code>jdbc</code> , <code>ansi</code> , <code>dbms</code> , <code>default</code>  Controls the format in which the values of <code>DATE</code> , <code>TIME</code> and <code>TIMESTAMP</code> columns are written into the generated SQL statements. For a detailed description of the possible values, please refer to the <a href="#">WbExport</a> command.
<code>-ignoreColumns</code>	With this parameter you can define a list of column names that should not be considered when comparing data. You can e.g. exclude columns that store the last access time of a row, or the last update time if that should not be taken into account when checking for changes.
<code>-showProgress</code>	Valid values: <code>true</code> , <code>false</code> , <code>&lt;numeric value&gt;</code>  Control the update frequency in the statusbar (when running in GUI mode). The default is every 10th row is reported. To disable the display of the progress specify a value of 0 (zero) or the value <code>false</code> . <code>true</code> will set the progress interval to 1 (one).

## WbDataDiff Examples

Compare all tables between two connections, and write the output to the file `migrate_staging.sql`, but do not generate `DELETE` statements.

```
WbDataDiff -referenceProfile="Production"
           -targetProfile="Staging"
           -file=migrate_staging.sql
           -includeDelete=false
```

Compare a list of matching tables between two databases and write the output to the file `migrate_staging.sql` including `DELETE` statements.

```
WbDataDiff -referenceProfile="Production"
           -targetProfile="Staging"
           -referenceTables=person,address,person_address
           -file=migrate_staging.sql
           -includeDelete=true
```

Compare three tables that are differently named in the target database and ignore all columns (regardless in which table they appear) that are named `LAST_ACCESS` or `LAST_UPDATE`

```
WbDataDiff -referenceProfile="Production"
```

```

-targetProfile="Staging"
-referenceTables=person,address,person_address
-targetTables=t_person,t_address,t_person_address
-ignoreColumns=last_access,last_update
-file=migrate_staging.sql
-includeDelete=true

```

## 14.4. Search source of database objects - WbGrepSource

The command `WbGrepSource` can be used to search in the source code of the specified database objects.

The command basically retrieves the source code for all selected objects and does a simple search on that source code. The source code that is searched is identical to the source code that is displayed in the "Source" tab in the various DbExplorer panels.

The search values can be regular expressions. When searching the source code the specified expression must be found somewhere in the source. The regex is *not* used to match the *entire* source.

The command supports the following parameters:

Parameter	Description
-searchValues	A comma separated list of values to be searched for.
-useRegex	Valid values are <code>true</code> , <code>false</code> .  If this parameter is set to <code>true</code> , the values specified with <code>-searchValues</code> are treated as regular expression  The default for this parameter is <code>false</code> .
-matchAll	Valid values are <code>true</code> , <code>false</code> .  This specifies if all values specified with <code>-searchValues</code> have to match or only one.  The default for this parameter is <code>false</code> .
-ignoreCase	Valid values are <code>true</code> , <code>false</code> .  When set to <code>true</code> , the comparison is be done case-insensitive (" <code>ARTHUR</code> " will match " <code>Arthur</code> " or " <code>arthur</code> ").  The default for this parameter is <code>true</code> .
-types	Specifies if the object types to be searched. The values for this parameter are the same as in the "Type" drop down of DbExplorer's table list. Additionally the types <code>function</code> , <code>procedure</code> and <code>trigger</code> are supported.  When specifying a type that contains a space, the type name needs to be enclosed in quotes, e.g. <code>-types="materialized view"</code>  The default for this parameter is <code>view, procedure, function, trigger, materialized view</code> .  To search in all available object types, use <code>-types=*</code>
-objects	A list of object names to be searched. These names may contain SQL wildcards, e.g. <code>-objects=PER%,NO%</code>
-schemas	Specifies a list of schemas to be searched (for DBMS that support schemas). If this parameter is not specified the current schema is searched.

The functionality of the `WbGrepSource` command is also available through a GUI at Tools » Search in object source

## 14.5. Search data in multiple tables - WbGrepData

The command `WbGrepData` can be used to search for occurrences of a certain value in all columns of multiple tables. It is the commandline version of the (client side) [Search Table Data](#) tab in the DbExplorer. A more detailed description on how the searching is performed is available that chapter.

To search the data of a table a `SELECT * FROM the_table` is executed and processed on a row by row basis. Although SQL Workbench/J only keeps one row at a time in memory it is possible that the JDBC drivers caches the full result set in memory. Please see the chapter [Common problems](#) for your DBMS to check if the JDBC driver you are using caches result sets.

The command supports the following parameters:

Parameter	Description
<code>-search</code>	The value to be searched for
<code>-ignoreCase</code>	Valid values are <code>true</code> , <code>false</code> .  When set to <code>true</code> , the comparison is be done case-insensitive ("ARTHUR" will match "Arthur" or "arthur").  The default for this parameter is <code>true</code> .
<code>-compareType</code>	Valid values are <code>contains</code> , <code>equals</code> , <code>matches</code> , <code>startsWith</code>  When specifying matches, the search value is used as a regular expression. A column is included in the search result if the regular expression is contained in the column value (not when the column value matches the regular expression entirely!).  The default for this parameter is <code>contains</code> .
<code>-tables</code>	A list of table names to be searched. These names may contain SQL wildcards, e.g. <code>-tables=PER%,NO%</code> . If you want to search in different schemas, you need to prefix the table names, e.g. <code>-tables=schema1.p%,schema2.n%</code> .
<code>-types</code>	By default <code>WbGrepData</code> will search all tables and views (including materialized views). If you want to search only one of those types, this can be specified with the <code>-types</code> parameter. Using <code>-types=table</code> will only search table data and skip views in the database.
<code>-excludeTables</code>	A list of table names to be excluded from the search. If e.g. the wildcard for <code>-tables</code> would select too many tables, you can exclude individual tables with this parameter. The parameter values may include SQL wildcards.  <code>-tables=p% -excludeTables=product_details,product_images</code> would process all tables starting with P but not the <code>product_detail</code> and the <code>product_images</code> tables.
<code>-excludeLobs</code>	If this parameter is set to <code>true</code> , CLOB and BLOB columns will not be retrieved at all, which is useful if you retrieve a lot of rows from tables with columns of those type to reduce the memory that is needed.  If this switch is set to <code>true</code> the content of CLOB columns will not be searched.

## 14.6. Define a script variable - WbVarDef

This defines an internal variable which is used for variable substitution during SQL execution. Details can be found in the chapter Variable substitution.

The syntax for defining a variable is: `WbVarDef variable=value`

The variable definition can also be read from a file. The file should list each variable definition on one line (this is the format of a normal Java properties file). Lines beginning with a # sign are ignored. The syntax is `WBVARDEF - file=<filename>`

You can also specify a file when starting SQL Workbench/J with the parameter `-vardef=filename.ext`. When specifying a filename you can also define an encoding for the file using the `-encoding` switch. The specified file has to be a regular Java properties file. For details see [Reading variables from a file](#).

## 14.7. Delete a script variable - WbVarDelete

This removes an internal variable from the variable list. Details can be found in the chapter Variable substitution.

## 14.8. Show defined script variables - WbVarList

This list all defined variables from the variable list. Details can be found in the chapter Variable substitution.

## 14.9. Confirm script execution - WbConfirm

The `WbConfirm` command pauses the execution of the current script and displays a message. You can then choose to stop the script or continue. The message can be supplied as a parameter of the command. If no message is supplied, a default message is displayed.

This command can be used to prevent accidental execution of a script even if [confirm updates](#) is not enabled.

This command has no effect in batch mode.

## 14.10. Run a stored procedure with OUT parameters - WbCall

If you want to run a stored procedure that has OUT parameters, you have to use the `WbCall` command to correctly see the returned value of the parameters.

Consider the following (Oracle) procedure:

```
CREATE OR REPLACE procedure return_answer(answer OUT integer)
IS
BEGIN
    answer := 42;
END;
/
```

To call this procedure you need to supply a placeholder indicating that a parameter is needed.

```
SQL> WbCall return_answer(?);
PARAMETER | VALUE
-----+-----
```

ANSWER | 42

(1 Row)

Converted procedure call to JDBC syntax: {call return\_answer(?)}

Execution time: 0.453s

SQL&gt;

## Stored procedures with REF CURSORS

If the stored procedure has a REF CURSOR (as an output parameter), WbCall will detect this, and retrieve the result of the ref cursors.

Consider the following (Oracle) stored procedure:

```
CREATE PROCEDURE ref_cursor_example(pid number, person_result out sys_refcursor, addr_resu
BEGIN
    OPEN person_result FOR
        SELECT *
        FROM person
        WHERE person_id = pid;

    OPEN addr_result FOR
        SELECT a.*
        FROM address a JOIN person p ON a.address_id = p.address_id
        WHERE p.person_id = pid;
END;
/
```

To call this procedure you use the same syntax as with a regular OUT parameter:

```
WbCall ref_cursor_example(42, ?, ?);
```

SQL Workbench/J will display two result tabs, one for each cursor returned by the procedure. If you use WbCall `ref_cursor_example(?, ?, ?)` you will be prompted to enter a value for the first parameter (because that is an IN parameter).

## PostgreSQL functions that return a refcursor

When using ref cursors in PostgreSQL, normally such a function can simply be used inside a SELECT statement, e.g. `SELECT * FROM refcursorfunc()`. Unfortunately the PostgreSQL JDBC driver does not handle this correctly and you will not see the result set returned by the function.

To display the result set returned by such a function, you have to use WbCall as well

```
CREATE OR REPLACE FUNCTION refcursorfunc()
    RETURNS refcursor
AS
$$
DECLARE
    mycurs refcursor;
BEGIN
    OPEN mycurs FOR SELECT * FROM PERSON;
    RETURN mycurs;
END;
$$ LANGUAGE plpgsql;
/
```

You can call this function using

```
WbCall refcursorfunc();
```

This will then display the result from the SELECT inside the function.

## 14.11. Execute a SQL script - WbInclude (@)

With the `WbInclude` command you run SQL scripts without actually loading them into the editor, or call other scripts from within a script. The format of the command is `WbInclude -file=filename;`. For DBMS other than MS SQL, the command can be abbreviated using the @ sign: `@filename;` is equivalent to `WbInclude -file=filename;`. The called script may also include other scripts. Relative files (e.g. as parameters for SQL Workbench/J commands) in the script are always resolved to the directory where the script is located, not the current directory of the application.

The reason for excluding MS SQL is, that when creating stored procedures in MS SQL, the procedure parameters are identified using the @ sign, thus SQL Workbench/J would interpret the lines with the variable definition as the `WbInclude` command. If you want to use the @ command with MS SQL, you can [configure](#) this in your `workbench.settings` configuration file.

If the included SQL script contains SELECT queries, the result of those queries will **not** be displayed in the GUI

The long version of the command accepts additional parameters. When using the long version, the filename needs to be passed as a parameter as well.

Only files up to a [certain size](#) will be read into memory. Files exceeding this size will be processed statement by statement. In this case the automatic detection of the [alternate delimiter](#) [37] will not work. If your scripts exceed the maximum size and do use the alternate delimiter you will have to use the "long" version so that you can specify the actual delimiter used in your script.

The command supports the following parameters:

Parameter	Description
-file	The filename of the file to be included.
-continueOnError	Defines the behaviour if an error occurs in one of the statements. If this is set to <code>true</code> then script execution will continue even if one statement fails. If set to <code>false</code> script execution will be halted on the first error. The default value is <code>false</code>
-delimiter	Specify the delimiter that is used in the script. This defaults to <code>;</code> . If you want to define a delimiter that will only be recognized when it's the only text in a line, append <code>:nl</code> to the value, e.g.: <code>-delimiter=:nl</code>
-encoding	Specify the encoding of the input file. If no encoding is specified, the default encoding for the current platform (operating system) is used.
-verbose	Controls the logging level of the executed commands. <code>-verbose=true</code> has the same effect as adding a <code>WbFeedback on</code> inside the called script. <code>-verbose=false</code> has the same effect as adding the statement <code>WbFeedback off</code> to the called script.
-useSavepoint	Control if each statement from the file should be guarded with a savepoint when executing the script. Setting this to <code>true</code> will make execution of the script more robust, but also slows down the processing of the SQL statements.
-ignoreDropErrors	Controls if errors resulting from DROP statements should be treated as an error or as a warning.

Execute `my_script.sql`

```
@my_script.sql;
```

Execute `my_script.sql` but abort on the first error

```
wbinclude -file="my_script.sql" -continueOnError=false;
```

## 14.12. Extract and run SQL from a Liquibase ChangeLog - WbRunLB

If you manage your stored procedures in Liquibase ChangeLogs, you can use this command to run the necessary SQL directly from the XML file, without the need to copy and paste it into SQL Workbench/J. This is useful when testing and developing stored procedures that are managed by a Liquibase changeLog.

This is NOT a replacement for Liquibase.

WbRunLB will only extract SQL statements stored in `<sql>` or `<createProcedure>` tags.

It will not convert any of the Liquibase tags to "real" SQL.

WbRunLB will **NOT** update the Liquibase log table (DATABASECHANGELOG) nor will it check if the specified changeSet(s) have already been applied to the database.

It is merely a convenient way to extract and run SQL statements stored in a Liquibase XML file!

The attribute `splitStatements` for the `sql` tag is evaluated. The delimiter used to split the statements follows the usual SQL Workbench/J rules (including the use of the [alternate delimiter](#)).

WbRunLB supports the following parameters:

Parameter	Description
-file	The filename of the Liquibase changeLog (XML) file. The <code>&lt;include&gt;</code> tag is NOT supported! SQL statements stored in files that are referenced using Liquibase's <code>include</code> tag will not be processed.
-changeSet	A list of changeSet ids to be run. If this is omitted, then the SQL from all changesets (containing ) are executed. The value specified can include the value for the author attribute as well, <code>-changeSet="Arthur;42"</code> selects the changeSet where <code>author="Arthur"</code> and <code>id="42"</code> . This parameter can be repeated in order to select multiple changesets: <code>-changeSet="Arthur;42" -changeSet="Arthur;43"</code> .
-author	Select all changeSets with a given author, e.g. <code>-author=Arthur</code> . If this parameter is specified, <code>-changeSet</code> is ignored. This parameter can be repeated in order to select changesets from multiple authors: <code>-author=Arthur -author=Zaphod</code> .
-continueOnError	Defines the behaviour if an error occurs in one of the statements. If this is set to <code>true</code> then script execution will continue even if one statement fails. If set to <code>false</code> script execution will be halted on the first error. The default value is <code>false</code>
-encoding	Specify the encoding of the input file. If no encoding is specified, UTF-8 is used.

## 14.13. Handling tables or updateable views without primary keys

### 14.13.1. Define primary key columns - WbDefinePK

To be able to directly edit data in the result set (grid) SQL Workbench/J needs a primary key on the underlying table. In some cases these primary keys are not present or cannot be retrieved from the database (e.g. when using updateable views). To still be able to automatically update a result based on those tables (without always manually defining the primary key) you can manually define a primary key using the `WbDefinePk` command.

Assuming you have an updateable view called `v_person` where the primary key is the column `person_id`. When you simply do a `SELECT * FROM v_person`, SQL Workbench/J will prompt you for the primary key when you try to save changes to the data. If you run

```
WbDefinePk v_person=person_id
```

before retrieving the result, SQL Workbench/J will automatically use the `person_id` as the primary key (just as if this information had been retrieved from the database).

To delete a definition simply call the command with an empty column list:

```
WbDefinePk v_person=
```

If you want to define certain mappings permanently, this can be done using a mapping file that is specified in the [configuration file](#). The file specified has to be a text file with each line containing one primary key definition in the same format as passed to this command. The global mapping will automatically be saved when you exit the application if a filename has been defined. If no file is defined, then all PK mappings that you define are lost when exiting the application (unless you explicitly save them using [WbSavePkMap](#)

```
v_person=person_id
v_data=id1,id2
```

will define a primary key for the view `v_person` and one for the view `v_data`. The definitions stored in that file can be overwritten using the `WbDefinePk` command, but those changes won't be saved to the file. This file will be read for all database connections and is not profile specific. If you have conflicting primary key definitions for different databases, you'll need to execute the `WbDefinePk` command each time, rather than specifying the keys in the mapping file.

When you define the key columns for a table through the GUI, you have the option to remember the defined mapping. If this option is checked, then that mapping will be added to the global map (just as if you had executed `WbDefinePk` manually.

The mappings will be stored with lowercase table names internally, regardless how you specify them.

### 14.13.2. List defined primary key columns - `WbListPKDef`

To view the currently defined primary keys, execute the command `WbListPkDef`.

### 14.13.3. Load primary key mappings - `WbLoadPKMap`

To load the additional primary key definitions from a file, you can use the `WbLoadPKMap` command. If a filename is defined in the [configuration file](#) then that file is loaded. Alternatively if no file is configured, or if you want to load a different file, you can specify the filename using the `-file` parameter.

### 14.13.4. Save primary key mappings - `WbSavePKMap`

To save the current primary key definitions to a file, you can use the `WbSavePKMap` command. If a filename is defined in the [configuration file](#) then the definition is stored in that file. Alternatively if no file is configured, or if you want to store the current mapping into a different file, you can specify the filename using the `-file` parameter.

## 14.14. Change the default fetch size - `WbFetchSize`

The default fetch size for a connection can be defined in the [connection profile](#). Using the command `WbFetchSize` you can change the fetch size without changing the connection profile.

The following script changes the default fetch size to 2500 rows and then runs a `WbExport` command.

```
WbFetchSize 2500;  
WbExport -sourceTable=person -type=text -file=/temp/person.txt;
```

`WbFetchSize` will not change the current connection profile.

### 14.15. Run statements as a single batch - `WbStartBatch`, `WbEndBatch`

To send several SQL Statements as a single "batch" to the database server, the two commands `WbStartBatch` and `WbEndBatch` can be used. All statements between these two will be sent as a single statement (using `executeBatch()`) to the server.

Note that not all JDBC drivers support batched statements, and the flexibility what kind of statements can be batched varies between the drivers as well. Most drivers will not accept different types of statements e.g. mixing `DELETE` and `INSERT` in the same batch.

To send a group of statements as a single batch, simply use the command `WbStartBatch` to mark the beginning and `WbEndBatch` to mark the end. You have to run all statements together either by using "Execute all" or by selecting all statements (including `WbStartBatch` and `WbEndBatch`) and then using "Execute selected". The following example sends all `INSERT` statements as a single batch to the database server:

```
WbStartBatch;  
INSERT INTO person (id, firstname, lastname) VALUES (1, 'Arthur', 'Dent');  
INSERT INTO person (id, firstname, lastname) VALUES (2, 'Ford', 'Prefect');  
INSERT INTO person (id, firstname, lastname) VALUES (3, 'Zaphod', 'Beeblebrox');  
INSERT INTO person (id, firstname, lastname) VALUES (4, 'Tricia', 'McMillian');  
WbEndBatch;  
COMMIT;
```

### 14.16. Extracting BLOB content - `WbSelectBlob`

To save the contents of a BLOB or CLOB column into an external file the `WbSelectBlob` command can be used. Most DBMS support reading of CLOB (character data) columns directly, so depending on your DBMS (and JDBC driver) this command might only be needed for binary data.

The syntax is very similar to the regular `SELECT` statement, an additional `INTO` keyword specifies the name of the external file into which the data should be written:

```
WbSelectBlob blob_column  
INTO c:/temp/image.bmp  
FROM theTable  
WHERE id=42;
```

Even if you specify more than one column in the column list, SQL Workbench/J will only use the first column. If the `SELECT` returns more than one row, then one outputfile will be created for each row. Additional files will be created with a counter indicating the row number from the result. In the above example, `image.bmp`, `image_1.bmp`, `image_3.bmp` and so on, would be created.

`WbSelectBlob` is intended for an ad-hoc retrieval of a single LOB column. If you need to extract the contents of several LOB rows and columns it is recommended to use the [WbExport](#) command.

You can also manipulate (save, view, upload) the contents of BLOB columns in a result set. Please refer to BLOB support for details.

## 14.17. Control feedback messages - WbFeedback

Normally SQL Workbench/J prints the results for each statement into the message panel. As this feedback can slow down the execution of large scripts, you can disable the feedback using the `WbFeedback OFF` command. When `WbFeedback OFF` is executed, only a summary of the number of executed statements will be displayed, once the script execution has finished. This is the same behaviour as selecting "Consolidate script log" in the options window. The only difference is, that the setting through `WbFeedback` is temporary and does not affect the global setting.

## 14.18. Setting connection properties - SET

The `SET` command is passed on directly to the driver, except for the parameters described in this chapter as they have an equivalent JDBC call which will be executed instead.

Oracle does not have a SQL set command. The `SET` command that is available in SQL\*Plus is a specific SQL\*Plus command and will not work with other client software. Most of the SQL\*Plus `SET` commands only make sense with SQL\*Plus (e.g. formatting of the results). To be able to run SQL scripts that are intended for Oracle SQL\*Plus, any error reported from the `SET` command when running against an Oracle database will silently be ignored and only logged as a warning.

### 14.18.1. FEEEDBACK

`SET feedback ON/OFF` is equivalent to the [WbFeedback](#) command, but mimics the syntax of Oracle's SQL\*Plus utility.

### 14.18.2. SERVEROUTPUT

`SET serveroutput on` is equivalent to the [ENABLEOUT](#) command and `SET serveroutput off` is equivalent to [DISABLEOUT](#) command.

### 14.18.3. AUTOCOMMIT

With the command `SET autocommit ON/OFF` autocommit can be turned on or off for the current connection. This is equivalent to setting the autocommit property in the [connection profile](#) or toggling the state of the SQL » Autocommit menu item.

### 14.18.4. MAXROWS

Limits the number of rows returned by the next statement. The behaviour of this command is a bit different between the console mode and the GUI mode. In console mode, the maxrows stay in effect until you explicitly change it back using `SET maxrows` again.

In GUI mode, the maxrows setting is only in effect for the script currently being executed and will only temporarily overwrite any value entered in the "Max. Rows" field.

## 14.19. Changing read only mode - WbMode

In the [connection profile](#) two options can be specified to define the behaviour when running commands that might change the update: a "read only" mode that ignores such commands and a "confirm all" mode, where you need to confirm any statement that might change the database.

These states can temporarily be changed without actually changing the profile using the `WbMode` command.

This changes the mode for all editor tabs, not only for the one where you run the command.

Parameters for the WbMode command are:

reset	Resets the flags to the profile's definition
normal	Makes all changes possible (turns off read only and confirmations)
confirm	Enables confirmation for all updating commands
readonly	Turns on the read only mode

The following example will turn on read only mode for the current connection, so that any subsequent statement that updates the database will be ignored

```
WbMode readonly;
```

To change the current connection back to the settings from the profile use:

```
WbMode reset;
```

## 14.20. Show table structure - DESCRIBE

Describe shows the definition of the given table. It can be abbreviated with DESC. The command expects the table name as a parameter. The output of the command will be several result tabs to show the table structure, indexes and triggers (if present). If the "described" object is a view, the message tab will additionally contain the view source (if available).

```
DESC person;
```

If you want to show the structure of a table from a different user, you need to prefix the table name with the desired user  
`DESCRIBE otheruser.person;`

## 14.21. List tables - WbList

This command lists all available tables (including views and synonyms). This output is equivalent to the left part of the Database Object Explorer's Table tab.

You can limit the displayed objects by either specifying a wildcard for the names to be retrieved: `WbList P%` will list all tables or views starting with the letter "P"

The command supports two parameters to specify the tables and objects defined in a more detailed manner. If you want to limit the result by specifying a wildcard for the name **and** the object type, you have to use the parameter switches:

Parameter	Description
-objects	Select the objects to be returned using a wildcard name, e.g. <code>-objects=P%</code>
-types	Limit the result to specific object types, e.g. <code>WbList -objects=V% -types=VIEW</code> will return all views starting with the letter "V".

## 14.22. List stored procedures - WbListProcs

This command will list all stored procedures available to the current user. The output of this command is equivalent to the Database Explorer's Procedure tab.

You can limit the list by supplying a wildcard search for the name, e.g.:

```
WbListProcs public.p%
```

### 14.23. List triggers - WbListTriggers

This command will list all stored triggers available to the current user. The output of this command is equivalent to the Database Explorer's Triggers tab (if enabled)

### 14.24. Show the source of a stored procedures - WbProcSource

This command will show the source for a single stored procedure (if the current DBMS is supported by SQL Workbench/J). The name of the procedure is given as an argument to the command:

```
WbProcSource theAnswer
```

### 14.25. List catalogs - WbListCat

Lists the available catalogs (or databases). It is the same information that is shown in the DbExplorer's "Database" dropdown.

The output of this command depends on the underlying JDBC driver and DBMS. For MS SQL Server this lists the available databases (which then could be changed with the command `USE <dbname>`)

For Oracle this command returns nothing as Oracle does not implement the concept of catalogs.

This command calls the JDBC driver's `getCatalogs()` method and will return its result. If on your database system this command does not display a list, it is most likely that your DBMS does not support catalogs (e.g. Oracle) or the driver does not implement this feature.

This command ignores the filter defined for catalogs in the [connection profile](#) and always returns all databases.

### 14.26. List schemas - WbListSchemas

Lists the available schemas from the current connection. The output of this command depends on the underlying JDBC driver and DBMS. It is the same information that is shown in the DbExplorer's "Schema" dropdown.

This command ignores the filter defined for schemas in the [connection profile](#) and always returns all schemas.

### 14.27. Change the connection for a script - WbConnect

With the `WbConnect` command, the connection for the script that is currently be executed can be changed.

When this command is run in GUI mode, the connection is **only** changed for the remainder of the script execution. Therefor at least one other statement should be executed together with the `WbConnect` command. Either by running the complete script of the editor or selecting the `WbConnect` command together with other statements. Once the script has finished, the connection is closed and the "global" connection (selected in the connect dialog) is active again. This also applies to scripts that are run in [batch mode](#) or scripts that are started from within the console using [WbInclude](#).

When this command is entered directly in the commandline of the [console mode](#), the current connection is closed and the new connection is kept open until the application ends, or a new connection is established using `WbConnect` on the commandline again.

The command supports the following parameters:

Parameter	Description
<code>-profile</code>	Defines the profile to connect to. If this parameter is specified all other parameters are ignored.
or	
<code>-url</code>	The JDBC connection URL
<code>-username</code>	Specify the username for the DBMS
<code>-password</code>	Specify the password for the user
<code>-driver</code>	Specify the full class name of the JDBC driver
<code>-driverJar</code>	Specify the full pathname to the .jar file containing the JDBC driver
<code>-autocommit</code>	Set the autocommit property for this connection. You can also control the autocommit mode from within your script by using the <a href="#">SET AUTOCOMMIT</a> command.
<code>-rollbackOnDisconnect</code>	If this parameter is set to true, a ROLLBACK will be sent to the DBMS before the connection is closed. This setting is also available in the <a href="#">connection profile</a> .
<code>-trimCharData</code>	Turns on right-trimming of values retrieved from CHAR columns. See the <a href="#">description</a> of the profile properties for details.
<code>-removeComments</code>	This parameter corresponds to the <a href="#">Remove comments</a> setting of the connection profile.
<code>-fetchSize</code>	This parameter corresponds to the <a href="#">Fetch size</a> setting of the connection profile.
<code>-ignoreDropError</code>	This parameter corresponds to the <a href="#">Ignore DROP errors</a> setting of the connection profile.

If none of the parameters is supplied when running the command, it is assumed that any value after `WbConnect` is the name of a connection profile, e.g.:

```
WbConnect production
```

will connect using the profile name `production`, and is equivalent to

```
WbConnect -profile=production
```

## 14.28. Run an XSLT transformation - `WbXslt`

Transforms an XML file via a XSLT stylesheet. This can be used to format XML input files into the correct format for SQL Workbench/J or to transform the output files that are generated by the various SQL Workbench/J commands.

Parameters for the XSLT command:

Parameter	Description
<code>-inputfile</code>	The name of the XML source file.
<code>-xsltoutput</code>	The name of the generated output file.
<code>-stylesheet</code>	The name of the XSLT stylesheet to be used.

Parameter	Description
-xsltParameters	A list of parameters (key/value pairs) that should be passed to the XSLT processor. When using e.g. the <code>wbreport2liquibase.xslt</code> stylesheet, the value of the <code>author</code> attribute can be set using <code>-xsltParameters="authorName=42"</code> .

## 14.29. Using Oracle's DBMS\_OUTPUT package

To turn on support for Oracle's DBMS\_OUTPUT package you have to use the (SQL Workbench/J specific) command `ENABLEOUT`.

After running `ENABLEOUT` the DBMS\_OUTPUT package is enabled, and any message written with `dbms_output.put_line()` is displayed in the message pane after executing a SQL statement. It is equivalent to calling the `dbms_output.enable()` procedure.

You can control the buffer size of the DBMS\_OUTPUT package by passing the desired buffer size as a parameter to the `ENABLEOUT` command: `ENABLEOUT 32000;`

Due to a bug in Oracle's JDBC driver, you cannot retrieve columns with the `LONG` or `LONG RAW` data type if the DBMS\_OUTPUT package is enabled. In order to be able to display these columns support for DBMS\_OUTPUT has to be switched off.

To disable the DBMS\_OUTPUT package again, use the (SQL Workbench/J specific) command `DISABLEOUT`. This is equivalent to calling `dbms_output.disable()` procedure.

## 15. DataPumper

### 15.1. Overview

The export and import features are useful if you cannot connect to the source and the target database at once. If your source and target are both reachable at the same time, it is more efficient to use the DataPumper to copy data between two systems. With the DataPumper no intermediate files are necessary. Especially with large tables this can be an advantage.

To open the DataPumper, select Tools » DataPumper

The DataPumper lets you copy data from a single table (or SELECT query) to a table in the target database. The mapping between source columns and target columns can be specified as well

Everything that can be done with the DataPumper, can also be accomplished with the [WbCopy](#) command. The DataPumper can also generate a script which executes the WbCopy command with the correct parameters according to the current settings in the window. This can be used to create scripts which copy several tables.

The DataPumper can also be started as a stand-alone application - without the main window - by specifying `-datapumper=true` in the command line when starting SQL Workbench/J. You can also use the supplied Windows executable `DataPumper.exe` or the Linux/Unix shell script `datapumper`

When opening the DataPumper from the main window, the main window's current connection will be used as the initial source connection. You can disable the automatic connection upon startup with the property `workbench.datapumper.autoconnect` in the `workbench.settings` file.

### 15.2. Selecting source and target connection

The DataPumper window is divided in three parts: the upper left part for defining the source of the data, the upper right part for defining the target, and the lower part to adjust various settings which influence the way, the data is copied.

After you have opened the DataPumper window it will automatically connect the source to the currently selected connection from the main window. If the DataPumper is started as a separate application, no initial connection will be made.

To select the source connection, press the ellipsis right next to the source profile label. The standard connection dialog will appear. Select the connection you want to use as the source, and click OK. The DataPumper will then connect to the database. Connecting to the target database works similar. Simply click on the ellipsis next to the target profile box.

Instead of a database connection as the source, you can also select a text or XML file as the source for the DataPumper. Thus it can also be used as a replacement of the [WbImport](#) command.

The dropdown for the target table includes an entry labelled "(Create new table)". For details on how to create a new table during the copy process please refer to the [advanced tasks](#) section.

After source and target connection are established you can specify the tables and define the column mapping between the tables.

### 15.3. Copying a complete table

To copy a single table select the source and target table in the dropdowns (which are filled as soon as the connection is established)

After both tables are selected, the middle part of the window will display the available columns from the source and target table. This grid display represents the column mapping between source and target table.

### 15.3.1. Mapping source to target columns

Each row in the display maps a source column to a target column. Initially the DataPumper tries to match those columns which have the same name and data type. If no match is found for a target column, the source column will display (Skip target column) This means that the column from the target table will not be included when inserting data into the target table (technically speaking: it will be excluded from the column list in the INSERT statement).

### 15.3.2. Restricting the data to be copied

You can restrict the number of rows to be copied by specifying a WHERE clause which will be used when retrieving the data from the source table. The WHERE clause can be entered in the SQL editor in the lower part of the window.

### 15.3.3. Deleting all rows from the target table

When you select the option "Delete target table", all rows from the target table will be deleted before the copy process is started. This is done with a `DELETE FROM <tablename>;` When you select this option, make sure the data can be deleted in this way, otherwise the copy process will fail.

The DELETE will not be committed right away, but at the end of the copy process. This is obviously only of interest if the connection is not done with `autocommit = true`

### 15.3.4. Continuing when an insert fails

In some cases inserting of individual rows in the target table might fail (e.g. a primary key violation if the table is not empty). When selecting the option "Continue on error", the copy process will continue even if rows fail to insert

### 15.3.5. Committing changes

By default all changes are committed at the end, when all rows have been copied. By supplying a value in the field "Commit every" SQL Workbench/J will commit changes every time the specified number of rows has been inserted into the target. When a value of 50 rows has been specified, and the source table contains 175 rows, SQL Workbench/J will send 4 COMMITs to the target database. After inserting row 50, row 100, row 150 and after the last row.

### 15.3.6. Batch execution

If the JDBC driver supports batch updates, you can enable the use of batch updates with this checkbox. The checkbox will be disabled, if the JDBC driver does not support batch updates, or if a combined update mode (insert,update, update,insert) is selected.

Batch execution is only available if either INSERT or UPDATE mode is selected.

### 15.3.7. Update mode

Just like the [WbImport](#) and [WbCopy](#) commands, the data pumper can optionally update the data in the target table. Select the appropriate update strategy from the Mode drop down. The DataPumper will use the key columns defined in the column mapper to generate the UPDATE command. When using update you have to select at least one key column.

You cannot use the update mode, if you select **only** key columns, The values from the source are used to build up the WHERE clause for the UPDATE statement. If any key columns are defined, then there would be nothing to update.

For maximum performance, choose the update strategy that will result in a successful first statement more often. As a rule of thumb:

- Use `-mode=insert , upadte`, if you expect more rows to be inserted then updated.
- Use `-mode=update , insert`, if you expect more rows to be updated then inserted.

## 15.4. Advanced copy tasks

### 15.4.1. Populating a column with a constant

To populate a target column with a constant value. The name of the source columns can be edited in order to supply a constant value instead of a column name. Any expression understood by the source database can be entered there. Note that if (Skip target column) is selected, the field cannot be edited.

### 15.4.2. Creating the target table

You can create the target table "on the fly" by selecting (`Create target table`) from the list of target tables. You will be prompted for the name of the new table. If you later want to use a different name for the table, click on the button to the right of the drop down.

The target table will be created without any primary key definitions, indexes or foreign key constraints.

The DataPumper tries to map the column types from the source columns to data types available on the target database. For this mapping it relies on information returned from the JDBC driver. The functions used for this may not be implemented fully in the driver. If you experience problems during the creation of the target tables, please create the tables manually before copying the data. It will work best if the source and target system are the same (e.g. PostgreSQL to PostgreSQL, Oracle to Oracle, etc).

Most JDBC drivers map a single JDBC data type to more than one native datatype. MySQL maps its `VARCHAR`, `ENUM` and `SET` type to `java.sql.Types.VARCHAR`. The DataPumper will take the first mapping which is returned by the driver and will ignore all subsequent ones. Any datatype that is returned twice by the driver is logged as a warning in the log file. The actual mappings used, are logged with type INFO.

To customize the mapping of generic JDBC datatypes to DBMS specific datatypes, please refer to [Customizing data type mapping](#)

### 15.4.3. Using a query as the source

If you want to copy the data from several tables into one table, you can use a `SELECT` query as the source of your data. To do this, select the option `Use SQL query as source` below the SQL editor. After you have entered your query into the editor, click the button `Retrieve columns from query`. The columns resulting from the query will then be put into the source part of the column mapping. Make sure, the columns are named uniquely when creating the query. If you select columns from different tables with the same name, make sure you use a column alias to rename the columns.

Creating the target table "on the fly" is not available when using a SQL query as the source of the data

## 16. Database Object Explorer

The Database Object Explorer displays the available database objects such as Tables, Views, Triggers and Stored Procedures.

There are three ways to start the DbExplorer

Using Tools » Database Explorer.

Passing the parameter `-dbexplorer` to the main program (`sqlworkbench.sh` or `SQLWorkbench.exe`)

When using Windows, with the `DbExplorer.exe` executable or in Linux/Unix using shell script `dbexplorer.sh`

At the top of the window, the current schema and/or catalog can be selected. Whether both dropdowns are available depends on the current DBMS. For Microsoft SQL Server, both the schema and the database can be changed. The labels next to the dropdown are retrieved from the JDBC driver and should reflect the terms used for the current DBMS (Schema for PostgreSQL and Oracle, Owner and Database for SQL Server, Database for MySQL).

The displayed list can be filtered using the quick filter above the list. To filter the list by the object name, simply enter the criteria in the filter field, and press `ENTER` or click the filter icon . The criteria field will list the last 25 values that were entered in the dropdown. If you want to filter based on a different column of the list, right-click on the criteria field, and select the desired column from the `Filtercolumn` menu item of the popup menu. The same filter can be applied on the `Procedures` tab.

The list of tables can be pre-filtered to remove unwanted entries such as tables that have been deleted and now reside in Oracle's "Recycle Bin". The filtering is done through a [regular expression](#) on a per-database basis. By default this is only defined for Oracle and will filter out any table that starts with `BIN$`.

Synonyms are displayed if the current DBMS supports them. You can filter out unwanted synonyms by [specifying a regular expression](#) in your `workbench.settings` file. This filter will also be applied when displaying the list of available tables when opening the [command completion](#) popup.

The first tab displays the structure of tables and views. The type of object displayed can be chosen from the drop down right above the table list. This list will be returned by the JDBC driver, so the available "Table types" can vary from DBMS to DBMS.

The menu item Database Explorer will either display the explorer as a new window or a new panel, depending on the [system options](#). If a DbExplorer is already open (either a window or a tab), the existing one is made visible (or active), when using this menu item.

You can open any number of additional DbExplorer tabs or windows using Tools » New DbExplorer panel or Tools » New DbExplorer window

### 16.1. Objects tab

The object list displays tables, views, sequences and synonyms (basically anything apart from procedures or functions). The context menu of the list offers several additional functions:

#### Export data

This will execute a [WbExport](#) command for the currently selected table(s). Choosing this option is equivalent to do a `SELECT * FROM table;` and then executing SQL » Export query result from the SQL editor in the main window. See the description of the [WbExport command](#) for details.

When using this function, the [customization for datatypes](#) is **not** applied to the generated `SELECT` statement.

## Put SELECT into

This will put a SELECT statement into the SQL editor to display all data for the selected table. You can choose into which editor tab the statement will be written. The currently selected editor tab is displayed in bold (when displaying the DbExplorer in a separate window). You can also put the generated SQL statement into a new editor tab, by selecting the item New tab

When using this function, the [customization for datatypes](#) **will be** applied to the generated SELECT statement.

## Create empty INSERT

This creates an empty INSERT statement for the currently selected table(s). This is intended for programmers that want to use the statement inside their code.

## Create default SELECT

This creates a SELECT for the selected table(s) that includes all columns for the table. This feature is intended for programmers who want to put a SELECT statement into their code.

If you want to generate a SELECT statement to actually retrieve data from within the editor, please use the [Put SELECT into](#) option.

When using this function, the [customization for datatypes](#) is **not** applied to the generated SELECT statement.

## Create DDL Script

With this command a script for multiple objects can be created. Select all the tables, views or other objects in the table list, that you want to create a script for. Then right click and select "Create DDL Script". This will generate one script for all selected items in the list.

When this command is selected, a new window will be shown. The window contains a statusbar which indicates the object that is currently processed. The complete script will be shown as soon as all objects have been processed. The objects will be processed in the order: SEQUENCES, TABLES, VIEWS, SYNONYMS.

## Create schema report

This will create an XML report of the selected tables. You will be prompted to specify the location of the generated XML file. This report can also be generated using the [WbSchemaReport](#) command.

## Drop

Drops the selected objects. If at least one object is a table, and the currently used DBMS supports cascaded dropping of constraints, you can enable cascaded delete of constraints. If this option is enabled SQL Workbench/J would generate e.g. for Oracle a DROP TABLE mytable CASCADE CONSTRAINTS. This is necessary if you want to drop several tables at the same time that have foreign key constraints defined.

If the current DBMS does not support a cascading drop, you can order the tables so that foreign keys are detected and the tables are dropped in the right order by clicking on the Check foreign keys button.

If the checkbox "Add missing tables" is selected, any table that should be dropped before any of the selected tables (because of foreign key constraints) will be added to the list of tables to be dropped.

## Delete data

Deletes all rows from the selected table(s) by executing a `DELETE FROM table_name;` to the server for each selected table. If the DBMS supports `TRUNCATE` then this can be done with `TRUNCATE` as well. Using `TRUNCATE` is usually faster as no transaction state is maintained.

The list of tables is sorted according to the sort order in the table list. If the tables have foreign key constraints, you can re-order them to be processed in the correct order by clicking on the Check foreign keys button.

If the checkbox "Add missing tables" is selected, any table that should be deleted before any of the selected tables (because of foreign key constraints) will be added to the list of tables.

## ALTER script

After you have changed the name of a table in the list of objects, you can generate and run a SQL script that will apply that change to the database.

For details please refer to the section [Changing table definitions](#)

## 16.2. Table details

When a table is selected, the right part of the window will display its column definition, the SQL statement to create the table, any index defined on that table (only if the JDBC driver returns that information), other tables that are referenced by the currently selected table, any table that references the currently selected table and any trigger that is defined on that table.

The column list will also display any comments defined for the column (if the JDBC driver returns the information). Oracle's JDBC driver does not return those comments by default. To enable the display of column comments (remarks) you have to supply an [extended property](#) in your connection profile. The property's name should be `remarksReporting` and the value should be set to `true`.

If the DBMS supports synonyms, the columns tab will display the column definition of the underlying table or view. The source tab will display the statement to re-create the synonym. If the underlying object of the synonym is a table, then indexes, foreign keys and triggers for that table will be displayed as well.

Note that if the synonym is for a view, those tabs will still be displayed, but will not show any information.

## Changing the table definition

You can edit the definition of the columns, add new columns or delete existing columns. To apply the changes, click on the ALTER table button.

For details please refer to the section [Changing table definitions](#)

## 16.3. Modifying the definition of database objects

### 16.3.1. Renaming objects

You can edit the name of the objects in the object list. Depending on the DBMS, you might be able to change the name of other database objects as well (e.g. SEQUENCES, VIEWS, ...).

For DBMS that support it, you can also edit the remarks column of the table to change the documentation.

If the editing the name or comment is rejected, the necessary SQL statements have not been configured for your DBMS. If your DBMS does support changing the object type in question, please send a mail with the necessary information to the support email address.

Once you have changed a name (or several) the menu item "ALTER script" in the context menu of the object list, will display a window with the necessary SQL statements to apply your changes. You can save the generated script to a file or run the statements directly from that window.

### 16.3.2. Changing column definitions

You can change the column name, datatype, default value or the nullable flag in the display of the table's details. If the necessary ALTER statements have been configured for your DBMS, you can generate and run an ALTER script to apply your changes. This is done by clicking on the ALTER table button.

If your changes are rejected when editing, the necessary SQL statements have not been configured for your DBMS. If your DBMS does support changing table columns, please send a mail with the necessary information to the support email address.

## 16.4. Table data

The data tab will display the data from the currently selected table. There are several options to configure the display of this tab. The `Autoload` check box, controls the retrieval of the data. If this is checked, then the data will be retrieved from the database as soon as the table is selected in the table list (and the tab is visible).

The data tab will also display a total row count of the table. As this display can take a while, the automatic retrieval of the row count can be disabled. To disable the automatic calculation of the table's rowcount, click on the Settings button and deselect the checkbox `Autoload table row count`. To calculate the table's row count when this is not done automatically, click on the Rows label. You can cancel the row count retrieval while it's running by clicking on the label again.

The data tab is only available if the currently selected objects is recognized as an object that can be "SELECTED". Which object types are included can be defined in the settings for SQL Workbench/J See [selectable object types](#) for details.

You can define a maximum number of rows which should be retrieved. If you enter 0 (zero) then all rows are retrieved. Limiting the number of rows is useful if you have tables with a lot of rows, where the entire table would not fit into memory.

In addition to the max rows setting, a second limit can be defined. If the total number of rows in the table exceeds this second limit, a warning is displayed, whether the data should be loaded.

This is useful when the max rows parameter is set to zero and you accidentally display a table with a large number of rows.

If the automatic retrieval is activated, then the retrieve of the data can be prevented by holding down the Shift key while switching to the data tab.

The data in the tab can be edited just like the data in the main window. To add or delete rows, you can either use the buttons on the toolbar in the upper part of the data display, or the popup menu. To edit a value in a field, simply double click that field, start typing while the field has focus (yellow border) or hit F2 while the field has focus.

## 16.5. Changing the display order of table columns

You can re-arrange the display order of the columns in the data tab using drag & drop. If you want to apply that column order whenever you display the table data, you can save the column order by right-clicking in the table header and then using the menu item Save column order. If the column order has not been changed, the menu item is disabled.

The column order will be stored using the fully qualified table name and the current connection's JDBC URL as the lookup key.

To reset the column order use the menu item Reset column order from the popup menu. This will revert the column order to the order in which the columns appear in the source table. The saved order will be deleted as well.

## 16.6. Customize data retrieval

When displaying the data for a table, SQL Workbench/J generates a `SELECT` statement that will retrieve all rows and columns from the database. In some cases the data for certain data types cannot be displayed correctly as the JDBC drivers might not implement a proper `toString()` method that converts the data into a readable format.

You can customize the `SELECT` statement that is generated by SQL Workbench/J when retrieving table data in the DbExplorer in the configuration file `workbench.settings`. For each DBMS you can define an expression for specific data types that are used when building the `SELECT` statement.

To configure this, you need to add one line per data type and DBMS to the file `workbench.settings`:

```
workbench.db.[dbid].selectexpression.[type]=expression(${column})
```

When building the `SELECT` statement, the placeholder `${column}` will be replaced with the actual column name. `[dbid]` is the [DBID](#) of the DBMS for which the replacement should be done.

The whole key (the part to the left of the equal sign) must be in lowercase.

`[type]` is the datatype of the column without any brackets or parameters: `varchar` instead of `varchar(10)`, or `number` instead of `number(10,2)`

To convert e.g. the geometry datatype of postgres to a readable format, one would use the following expression `astext(transform(geo_column,4326))`.

To tell the DbExplorer to replace the retrieval of columns of type `geometry` in PostgreSQL with the above expression, the following line in `workbench.settings` is necessary:

```
workbench.db.postgres.selectexpression.geometry=astext(transform(${column},4326))
```

For e.g. the table `geo_table (id integer, geo_col geometry)` SQL Workbench/J will generate the following `SELECT` statement:

```
SELECT id, astext(transform(geo_col,4326))
FROM geo_table
```

to retrieve the data of that table.

Note that the data of columns that have been "converted" through this mechanism, might not be updateable any more. If you intend to edit such a column you will have to provide a column alias in order for SQL Workbench/J to generate a correct `UPDATE` or `INSERT` statement.

Another example is to replace the retrieval of XML columns. To configure the DbExplorer to convert Oracle's `XMLTYPE` a string, the following line in `workbench.settings` is necessary:

```
workbench.db.oracle.selectexpression.xmltype=extract(${column}, '/').getClobVal()
```

To convert DB2's XML type to a string, the following configuration can be used:

```
workbench.db.db2.selectexpression.xml=xmlserialize(${column} AS CLOB)
```

The column name (as displayed in the result set) will usually be generated by the DBMS and will most probably not contain the real column name. In order to see the real column name you can supply a column alias in the configuration.

```
workbench.db.oracle.selectexpression.xmltype=extract(${column}, '/').getClobVal() AS ${col
```

In order for SQL Workbench/J to parse the SQL statement correctly, the AS keyword **must** be used.

You can check the generated SELECT statement by using the [Put SELECT into](#) feature. The statement that is generated and put into the editor, is the same as the one used for the data retrieval.

The defined expression will also be used for the [Search table data](#) feature, when using the server side search. If you want to search inside the data that is returned by the defined expression you have to make sure that your DBMS supports the result of that expression as part of a LIKE expression. E.g. for the above Oracle example, SQL Workbench/J will generate the following WHERE condition:

```
WHERE to_clob(my_clob_col) LIKE '%searchvalue%'
```

## 16.7. Customizing the generation of the table source

SQL Workbench/J re-generates the source of a table based on the information about the table's metadata returned by the driver. In some cases the driver might not return the correct information, or not all the information that is necessary to build the correct syntax for the DBMS. In those cases, a SQL query can be configured that can use the built-in functionality of the DBMS to return a table's definition.

This DBMS specific retrieval of the table source is defined by three properties in `workbench.settings`. Please refer to [Customize table source retrieval](#) for details.

## 16.8. View details

When a database VIEW is selected in the object list the right will display the columns for the view, the source and the data returned by a select from that view.

The data details tab works the same way as the data tab for a table. If the view is updateable (depends on the view definition and the underlying DBMS) then the data can also be changed within the data tab

The source code is retrieved by customized SQL queries (this is not supported by the JDBC driver). If the source code of views is not displayed for your DBMS, please contact <support@sql-workbench.net>.

## 16.9. Procedure tab

The procedure tab will list all stored procedures and functions stored in the current schema. For procedures or functions returning a result set, the definition of the columns will be displayed as well.

To display the procedure's source code SQL Workbench/J uses its own SQL queries. For most popular DBMS systems the necessary queries are built into the application. If the procedure source is not displayed for your DBMS, please contact the author.

Functions inside Oracle packages will be listed separately on the left side, but the source code will contain all functions/procedures from that package.

## 16.10. Search table data

This tab offers the ability to search for a value in all text columns of all tables which are selected. The results will be displayed on the right side of that tab. The result will always display the complete row where the search value was found. Any column that contains the entered value will be highlighted.

The results displayed here are not editable. If you want to modify the results after a search, you have to use the [WbGrepData](#) command

Two different implementations of the search are available: server side and client side.

### 16.10.1. Server side search

To server side search is enabled by selecting the checkbox labelled "Server side search".

The value will be used to create a `LIKE 'value'` restriction for each text column on the selected tables. Therefore the value should contain a wildcard, otherwise the exact expression will be searched.

You can apply a function to each column as well. This is useful if you want to do a case insensitive search on Oracle (Oracles `VARCHAR` comparison is case sensitive). In the entry field for the column the placeholder `$col$` is replaced with the actual column name during the search. To do a case insensitive search in Oracle, you would enter `lower($col$)` in the column field and `'%test%'` in the value field.

The expression in the column field is sent to the DBMS without changes, except the replacement of `$col$` with the current column name. The above example would yield a `lower(<column_name>) like '%test%'` for each text column for the selected tables.

The generated SQL statements are logged in the second tab, labeled `SQL Statements`.

In the resulting tables, SQL Workbench/J tries to highlight those columns which match the criteria. This might not always work, if you apply a function to the column itself such as `to_upper()`. SQL Workbench/J does not know that this will result in a case-insensitive search on the database. SQL Workbench/J tries to guess if the given function/value combination might result in a case insensitive search (especially on a DBMS which does a case sensitive search by default) but this might not work in all the cases and for all DBMS.

The `SELECT` statement that is built to display the table's data will list all columns from the table. If the table contains BLOB columns this might lead to a substantial memory consumption. To avoid loading too many data into memory, you can check the option "Do not retrieve LOB columns". In that case columns of type CLOB or BLOB will not be retrieved.

SQL Workbench/J is building a `SELECT` that "searches" for data using a `LIKE` expression. Only columns of type `CHAR` and `VARCHAR` are included in the `LIKE` search, because that is what most DBMS support. If the DBMS you are using supports `LIKE` expressions for other datatypes as well, you can [configure](#) this datatypes to be included in the search feature of the DbExplorer.

### 16.10.2. Client side search

To client side search is enabled by un-checking the checkbox labelled "Server side search".

The client side search retrieves every row from the server, compares the retrieved values for each row and keeps the rows where at least one column matches the defined search criteria.

As opposed to the server side search, this means that **every** row from the selected table(s) will be sent from the database server to the application. For large tables where only a small number of the rows will match the search value this can increase the processing time substantially.

As the searching is done on the client side, this means that it can also "search" data types that cannot be used for a `LIKE` query such as `CLOB`, `DATE`, `INTEGER`.

The search criteria is defined similar to the definition of a [filter](#) for a result set. For every column, its value will be converted to a character representation. The resulting string value will then be compared according to the defined comparator and the entered search value. If at least one column's value matches, the row will be displayed. The comparison is always done in a case-insensitively. The contents of BLOB columns will never be searched.

The character representation that is used is based on the default formatting options from the [Options Window](#). This means that e.g. a DATE column will be compared according to the standard formatting options before the comparison is done.

The client side search is also available through the [WbGrepData](#) command

## 17. Common problems

### 17.1. The driver class was not found

If you get an error "Driver class not registered" or "Driver not found" please check the following settings:

- Make sure you have specified the correct location of the jar file. Some drivers (e.g. for IBM DB2) may require more than one jar file.
- Check the spelling of the driver's class name. Remember that it's case sensitive. If you don't know the driver's class name, simply press the **Enter** key inside the input field of the jar file location. SQL Workbench/J will then scan the jar file(s) to find the JDBC driver

### 17.2. Syntax error when creating stored procedures

When creating a stored procedure (trigger, function) it is necessary to use a delimiter other than the normal semicolon because SQL Workbench/J does not know if a semicolon inside the stored procedure ends the procedure or simply a single statement inside the procedure.

Therefore you must use an alternate delimiter when running a DDL statement that contains "embedded" semicolons. For details please refer to [using the alternate delimiter](#).

### 17.3. Timestamps with timezone information are not displayed correctly

When using databases that support timestamps or time data with a timezone, the display in SQL Workbench/J might not always be correct, especially when daylight savings time (DST) is in effect.

This is caused by the handling of time data in Java and is usually *not* caused by the database, the driver or SQL Workbench/J

If your time data is not displayed correctly, you might try to explicitly specify the timezone when starting the application. This is done by passing the system property `-Duser.timezone=XYZ` to the application, where XYZ is the timezone where the computer is located that runs SQL Workbench/J

The timezone should be specified relative to GMT and not with a logical name. If you are in Germany and DST is active, you need to use `-Duser.timezone=GMT+2`. Specifying `-Duser.timezone=Europe/Berlin` does usually **not** work.

When using the [Windows launcher](#) you have to prefix the parameter with `-J` to identify it as a parameter for the Java runtime not for the application.

### 17.4. Excel export not available

In order to write the proprietary Microsoft Excel format, additional libraries are needed. Please refer to [Exporting Excel files](#) for details.

### 17.5. Out of memory errors

The memory that is available to the application is limited by the Java virtual machine to ensure that applications don't use all available memory which could potentially make a system unusable.

If you retrieve large resultsets from the database, you may receive an error message indicating that the application does not have enough memory to store the data.

Please refer to [Increasing the memory](#) for details on how to increase the memory that is available to SQL Workbench/J

## 17.6. Display problems when running under Windows®

If you experience problems when running SQL Workbench/J (or other Java/Swing based applications) on the Windows® platform, this might be due to problems with the graphics driver and/or the DirectDraw installation. If upgrading the graphics driver or the DirectDraw/DirectX version is not an option (or does not solve the problem), try to run SQL Workbench with the direct draw feature turned off:

```
java -Dsun.java2d.noddraw=true -jar sqlworkbench.jar
```

When using the exe launcher, you can use the following syntax:

```
SQLWorkbench -noddraw
```

If you run SQL Workbench/J through a program that enables remote access to a Windows® workstations (PC-Duo, VNC, NetMeeting, etc), you may need to disable the use of DirectDraw for Java as well.

## 17.7. High CPU usage when executing statements

If you experience a high CPU usage when running a SQL statement, this might be caused by a combination of the graphics driver, the JDK and the Windows® version you are using. This is usually caused by the animated icon which indicates a running statement (the yellow smiley). This animation can be turned off in Tools » Options See Enable animated icons for details. A different icon (not animated) will be used if that option is disabled.

## 17.8. Oracle Problems

### 17.8.1. Error: "Stream has already been closed"

Due to a bug in Oracle's JDBC driver, you cannot retrieve columns with the LONG or LONG RAW data type if the DBMS\_OUTPUT package is enabled. In order to be able to display these columns, the support for DBMS\_OUTPUT has to be switched off using the [DISABLEOUT](#) command before running a SELECT statement that returns LONG or LONG RAW columns.

### 17.8.2. BLOB support is not working properly

SQL Workbench/J supports reading and writing BLOB data in various ways. The implementation relies on standard JDBC API calls to work properly in the driver. If you experience problems when updating BLOB columns (e.g. using the [enhanced](#) UPDATE, INSERT syntax or the [DataPumper](#)) then please check the version of your Oracle JDBC driver. Only 10.x drivers implement the necessary JDBC functions properly. The version of your driver is reported in the log file when you make a connection to your Oracle server.

### 17.8.3. Table and column comments are not displayed

By default Oracle's JDBC driver does not return comments made on columns or tables (`COMMENT ON . .`). Thus your comments will not be shown in the database explorer.

To enable the display of column comments, you need to pass the property `remarksReporting` to the driver.

In the profile dialog, click on the Extended Properties button. Add a new property in the following window with the name `remarksReporting` and the value `true`. Now close the dialog by clicking on the OK button.

Turning on this features slows down the retrieval of table information e.g. in the Database Explorer.

When you have comments defined in your Oracle database and use the [WbSchemaReport](#) command, then you have to enable the remarks reporting, otherwise the comments will not show up in the report.

#### 17.8.4. Time for DATE columns is not displayed

A DATE column in Oracle always contains a time as well. If you are not seeing the time (or just 00:00:00) for a date column but you know there is a different time stored, please enable the option "Oracle DATE as Timestamp" in the "Data formatting" section of the Options dialog (Tools » Options)

#### 17.8.5. Content of XMLTYPE columns is not displayed

The content of columns with the data type XMLTYPE cannot be displayed by SQL Workbench/J because the Oracle JDBC driver does not support JDBC's XMLType and returns a proprietary implementation that can only be used with Oracle's XDB extension classes.

The only way to retrieve and update XMLType columns using SQL Workbench/J is to cast the columns to a CLOB value e.g. `CAST(xml_column AS CLOB)` or `to_clob(xml_column)`

In the DbExplorer you can customize the generated SQL statement to automatically convert the XMLType to a CLOB. Please refer to the chapter [Customize data retrieval in the DbExplorer](#) for details.

Note

#### 17.8.6. Error: "missing mandatory parameter"

When running statements that contain single line comments that are not followed by a space the following Oracle error may occur: `ORA-01009: missing mandatory parameter [SQL State=72000, DB Errorcode=1009]`.

```
--This is a comment  
SELECT 42 FROM dual;
```

When adding a space after the two dashes the statement works:

```
-- This is a comment  
SELECT 42 FROM dual;
```

This seems to be a problem with old Oracle JDBC drivers (such as the 8.x drivers). It is highly recommend to upgrade the driver to a more recent version (10.x or 11.x) as they not only fix this problems, but are in general much better than the old versions.

### 17.9. MySQL Problems

### 17.9.1. INFORMATION\_SCHEMA tables not displayed in DbExplorer

It seems that the necessary API calls to list the tables of the INFORMATION\_SCHEMA database (which is a database, not a schema - contrary to its name) are not implemented correctly in earlier JDBC drivers of MySQL. Only the driver with the version 5.1.7 returns the list of tables of the INFORMATION\_SCHEMA database.

### 17.9.2. "Operation not allowed" error message

In case you receive an error message "Operation not allowed after ResultSet closed" please upgrade your JDBC driver to a more recent version. This problem was fixed with the MySQL JDBC driver version 3.1. So upgrading to that or any later version will fix this problem.

### 17.9.3. Problems with zero dates with MySQL

MySQL allows the user to store invalid dates in the database (0000-00-00). Since version 3.1 of the JDBC driver, the driver will throw an exception when trying to retrieve such an invalid date. This behaviour can be controlled by adding an [extended property](#) to the connection profile. The property should be named `zeroDateTimeBehavior`. You can set this value to either `convertToNull` or to `round`. For details see <http://dev.mysql.com/doc/refman/4.1/en/connector-j-installing-upgrading.html>

### 17.9.4. Source SQL for views is not displayed

SQL Workbench/J retrieves the view definition from INFORMATION\_SCHEMA.VIEWS. In some cases the column VIEW\_DEFINITION does not contain the view definition and thus the source cannot be displayed.

## 17.10. Microsoft SQL Server Problems

### 17.10.1. Can't start a cloned connection while in manual transaction mode

This error usually occurs in the DbExplorer if an older Microsoft JDBC Driver is used and the connection does not use autocommit mode. There are three ways to fix this problem:

- Upgrade to a newer Microsoft driver (e.g. the one for [SQL Server 2005](#))
- Enable autocommit in the connection profile
- Add the parameter `;SelectMethod=Cursor` to your JDBC URL

This [article](#) in Microsoft's Knowledgebase gives more information regarding this problem.

The possible parameters for the SQL Server 2005 driver are listed here: <http://msdn2.microsoft.com/en-us/library/ms378988.aspx>

### 17.10.2. Dealing with locking problems

Microsoft SQL Server (at least up to 2000) does not support concurrent reads and writes to the database very well. Especially when using DDL statements, this can lead to database locks that can freeze the application. This affects e.g. the display of the tables in the DbExplorer. As the JDBC driver needs to issue a SELECT statement to retrieve the table information, this can be blocked by e.g. a non-committed CREATE . . . statement as that will lock the system table(s) that store the meta information about tables and views.

Unfortunately there is no real solution to blocking transactions e.g. between a SQL tab and the DbExplorer. One (highly discouraged) solution is to run in autocommit mode, the other to have only one connection for all tabs (thus all of them share the same transaction and the DbExplorer cannot be blocked by a different SQL tab).

The Microsoft JDBC Driver supports a connection property called `lockTimeout`. It is recommended to set that to 0 (zero) (or a similar low value). If that is done, calls to the driver's API will through an error if they encounter a lock rather than waiting until the lock is released. The jTDS driver does not support such a property. If you are using the jTDS driver, you can define a [post-connect script](#) that runs `SET LOCK_TIMEOUT 0`.

### 17.10.3. WbExport using a lot of memory

The jTDS driver and the Microsoft JDBC driver read the complete result set into memory before returning it to the calling application. This means that when retrieving data, SQL Workbench/J uses (for a short amount of time) twice as much memory as really needed. This also means that [WbExport](#) will effectively read the entire result into memory before writing it into the output file. For large exports this is usually not wanted.

This behaviour of the drivers can be changed by adding an additional parameter to the JDBC URL that is used to connect to the database. For the jTDS driver append `useCursors=true` to the URL, e.g. `jdbc:jtds:sqlserver://localhost:2068;useCursors=true`.

The URL parameters for the jTDS driver are listed here: <http://jtds.sourceforge.net/faq.html#urlFormat>

For the Microsoft driver, use the parameter `selectMethod=cursor` to switch to a cursor based retrieval that does not buffer all rows within the driver, e.g. `jdbc:sqlserver://localhost:2068;selectMethod=cursor`.

The URL parameters for the Microsoft driver are listed here: <http://msdn2.microsoft.com/en-us/library/ms378988.aspx>

## 17.11. DB2 Problems

### 17.11.1. "Connection closed" errors

When using the DB2 JDBC drivers it is important that the `charsets.jar` is part of the used JDK (or JRE). Apparently the DB2 JDBC driver needs this library in order to correctly convert the EBCDIC character set (used in the database) into the Unicode encoding that is used by Java. The library `charsets.jar` is usually included in all multi-language JDK/JRE installations.

If you experience intermittent "Connection closed" errors when running SQL statements, please verify that `charsets.jar` is part of your JDK/JRE installation. This file is usually installed in `jre\lib\charsets.jar`.

### 17.11.2. XML columns are not displayed properly in the DbExplorer

The content of columns with the data type XML are not displayed in the DbExplorer (but something like `com.ibm.db2.jcc.am.ie@1cee792` instead) because the driver does not convert them to a character datatype. To customize the retrieval for those columns, please refer to the chapter [Customize data retrieval in the DbExplorer](#).

When using a JDBC4 driver for DB2 (and Java 6), together with SQL Workbench/J build 107, XML content will be displayed directly without the need to cast the result.

### 17.11.3. No error text is displayed

When running SQL statements in SQL Workbench/J and an error occurs, DB2 does not show a proper error message. To enable the retrieval of error messages by the driver you have to set the [extended connection property](#) `retrieveMessagesFromServerOnGetMessage` to `true`.

The connection properties for the DB2 JDBC driver are documented here:

<http://publib.boulder.ibm.com/infocenter/db2luw/v9r7/index.jsp?topic=/com.ibm.db2.luw.apdv.java.doc/doc/r0052038.html>

<http://publib.boulder.ibm.com/infocenter/db2luw/v9r7/topic/com.ibm.db2.luw.apdv.java.doc/doc/r0052607.html>

The [example](#) claims that this property is only needed for z/OS, but it works as described for LUW as well.

#### 17.11.4. DB2 commands like REORG cannot be run

REORG, RUNSTATS and other db2 command line commands cannot be run directly through a JDBC interface because those are not SQL statements, but DB2 commands. To run such a command from with SQL Workbench/J you have to use the function `sysproc.admin_cmd()`. To run e.g. a REORG on a table you have to run the following statement:

```
call sysproc.admin_cmd('REORG TABLE my_table');
```

### 17.12. PostgreSQL Problems

#### 17.12.1. WbExport using a lot of memory

The PostgreSQL JDBC driver defaults to buffer the results obtained from the database in memory before returning them to the application. This means that when retrieving data, SQL Workbench/J uses (for a short amount of time) twice as much memory as really needed. This also means that [WbExport](#) will effectively read the entire result into memory before writing it into the output file. For large exports this is usually not wanted.

This behaviour of the driver can be changed so that the driver uses cursor based retrieval. To do this, the connection profile must disable the "Autocommit" option, and must define a default fetch size that is greater than zero. A recommended value is e.g. 10, it might be that higher numbers give a better performance. The number defined for the fetch size, defines the number of rows the driver keeps in its internal buffer before requesting more rows from the backend.

More details can be found in the driver's manual: <http://jdbc.postgresql.org/documentation/83/query.html#query-with-cursor>

#### 17.12.2. Getting the error: Current transaction is aborted

PostgreSQL - unlike other DBMS - marks a complete transaction as failed if a single statement fails. In such a case the transaction cannot be committed, e.g. consider the following script:

```
INSERT INTO person (id, firstname, lastname) VALUES (1, 'Arthur', 'Dent');
INSERT INTO person (id, firstname, lastname) VALUES (2, 'Zaphod', 'Beeblebrox');
INSERT INTO person (id, firstname, lastname) VALUES (2, 'Ford', 'Prefect');
COMMIT;
```

As the ID column is the primary key, the third insert will fail with a unique key violation. In PostgreSQL you cannot commit anyway and thus persist the first two INSERTs.

This problem can only be solved by using a SAVEPOINT before and after each statement. In case that statement fails, the transaction can be rolled back to the state before the statement and the remainder of the script can execute.

Doing this manually is quite tedious, so you can tell SQL Workbench/J to do this automatically for you by setting the properties:

```
workbench.db.postgresql.ddl.usesavepoint=true
```

```
workbench.db.postgresql.sql.usesavepoint=true
```

in the file [workbench.settings](#). If this is enabled, SQL Workbench/J will issue a `SET SAVEPOINT` before running each statement and will release the savepoint after the statement. If the statement failed, a rollback to the savepoint will be issued that will mark the transaction as "clean" again. So in the above example (with `sql.usesavepoint` set to `true`), the last statement would be rolled back automatically but the first two `INSERTs` can be committed (this will also required to turn on the "Ignore errors" option is enabled).

If you want to use the modes [update/insert](#) or [insert/update](#) for [WbImport](#), you should also add the property:

```
workbench.db.postgresql.import.usesavepoint=true
```

to enable the usage of savepoints during imports. This setting also affects the `WbCopy` command.

You can also use the parameter `-useSavepoint` for the `WbImport` and `WbCopy` commands to control the use of savepoints for each import.

Using savepoints can slow down the import substantially.

## 17.13. Sybase SQL Anywhere Problems

### 17.13.1. Columns with type `nvarchar` are not displayed properly

The `jConnect` driver seems to have a problem with `nvarchar` columns. The data type is not reported properly by the driver, so the display of the table structure in the `DbExplorer` will be wrong for those columns.

## 18. Options dialog

The options dialog enables you to influence the behaviour and look of SQL Workbench/J to meet your needs. To open the options dialog choose Tools » Options.

### 18.1. General options

#### 18.1.1. Language

With this option you can select in which language the application is shown. The new value will only be in affect when you restart the application.

#### 18.1.2. Check for updates

With this option you can enable an automatic update check when SQL Workbench/J is started. You can define the interval in days after which the application should check for updates on the homepage. If a newer version is found on the website this will be indicated with a little globe in the statusbar. Clicking on the icon will open your default internet browser with the application's homepage.

If you disable this option, you can manually check for updates using the menu Help » Check for updates....

When SQL Workbench/J performs an update check, it sends the following information as part of the request to the server:

- The version of SQL Workbench/J you are using
- Whether the check was an automatic check or a manual one
- The interface language selected
- The operating system as reported by your Java installation
- The Java version you are using

#### 18.1.3. Show connect dialog

If this option is enabled, the connect dialog will be shown automatically when the application is started.

#### 18.1.4. Exit on first connect cancel

If this option is enabled, then the application is closed completely if the initial connect dialog is cancelled.

This option is only valid if "Show connect dialog" is selected.

#### 18.1.5. Single page HTML help

If this option is enabled, the HTML help will be shown as a single page in the browser instead of one page per chapter.

#### 18.1.6. Encrypt passwords

If this option is enabled, the password stored within a connection profile will be encrypted. Whether the password should be stored at all can be selected in the profile itself.

Using this option only supplies very limited security. As the source code for SQL Workbench/J is freely available, the algorithm to decrypt the passwords stored in this way can easily be extracted to retrieve the plain text passwords.

### 18.1.7. Consolidate script log

Usually SQL Workbench/J reports the success and timings for each statement that is being executed in the message tab of the current SQL panel. For large scripts this can slow down script execution dramatically. If this option is enabled, only a summary of the execution is printed once the script has finished. You can turn off the log during script execution by using the [WBFEEDBACK](#) command.

### 18.1.8. Show tab index

If this option is enabled, each editor tab will be shown with its index. You can then select the first 9 tabs by pressing Ctrl-1, Ctrl-2 and so on.

### 18.1.9. Scroll tabs

This option controls the behaviour of the tab display, if more tabs are opened than can be displayed in the current width of the window.

If this option is enabled, the tabs are always displayed in a single row. If too many tabs are open, the row can be scrolled to display the tabs that are not visible.

If this option is disabled, the tabs are displayed in multiple rows, so that all tabs are always visible.

### 18.1.10. Confirm tab close

If this option is enabled, closing a tab needs to be confirmed, to prevent accidental closing.

### 18.1.11. Enable animated icons

Enable or disable the use of an animated icon in the SQL editor to indicate a running SQL statement. It has been reported, that the animated icon does have a severe (negative) impact on the performance on some computers (depending on JDK/OS/Graphics driver). If you experience a high CPU usage during the execution of SQL statements, or if you find your SQL statements are running very slow, try to turn off the usage of the animated icons.

### 18.1.12. Log Level

With this option you can control the level of information written to the application log. The most verbose level is DEBUG. With ERROR only severe errors (either resulting from running a user command or from an internal error) are written to the application log.

When using [Log4J](#) as the logger, this will change the log level of the root logger.

### 18.1.13. Configuration file information

At the bottom of the "General options" page, the full filename of the configuration file and the logfile are listed.

## 18.2. Editor options

### 18.2.1. Line ending for DBMS

This property controls the line terminator used by the editor when sending SQL statements to the database. The value "Platform default" relates to the platform where you run SQL Workbench/J this is not the platform of the DBMS server.

The editor always uses "unix" line ending internally. If you select a different value for this property, SQL Workbench/J will convert the SQL statements to use the desired line ending before sending them to the DBMS. As this can slow down the execution of statements, it is highly recommended to leave the default setting of Unix line endings. You should only change this, if your DBMS does not understand the single linefeed character (ASCII value 10) properly.

### **18.2.2. File format**

This property controls the line terminator used when a file is saved by the editor. Changing this property affects the next save operation.

### **18.2.3. Alternate Delimiter**

This options defines the default alternate delimiter. You can override this default in the connection profile, to use different delimiters for different DBMS. For details see [using the alternate delimiter](#)

### **18.2.4. History size**

The number of statements per tab which should be stored in the statement history. Remember that always the full text of the editor (together with the selection and cursor information) is stored in the history. If you have large amounts of text in the editor and set this number quite high, be aware of the memory consumption this might create.

### **18.2.5. Files in history**

If this option is enabled, the content of external files is also stored in the statement history.

### **18.2.6. Electric scroll**

Electric scrolling is the automatic scrolling of the editor when clicking into lines close to the upper or lower end of the editor window. If you click inside the defined number of lines at the upper or lower end, then the editor will scroll this line into the center of the visible area. The default is set to 3, which means that if you click into (visible) line 1,2 or 3 of the editor, this line will be centered in the display.

### **18.2.7. Editor tab width**

The number of spaces that are assumed for the TAB character.

### **18.2.8. Additional word characters**

The editor recognizes character sequences that consist of letters and characters only as "words". This influences the way word by word jumping is done, or when selecting text using a doubleclick. Every character that is entered for this option is considered a "word" character and thus does not mark a word boundary.

By putting e.g. an underscore into this field, the text MY\_TABLE is recognized as a single word instead of two words (which is the default).

### **18.2.9. Always allow "Execute Selected"**

If this option is turned off, then SQL » Execute Selected will only work if text is selected in the editor. If this option is turned on and no text is selected, the complete content of the editor will be executed.

### 18.2.10. Allow empty lines as statement delimiter

When analysing statements in the editor, it is assumed that individual statements are separated with a semicolon. This property controls if an empty line delimits a statement as well. This setting will be used to detect the current statement for auto-completion and when using "Execute Current" inside the editor.

This does not influence the behaviour when running scripts in batch mode or when using the `WbInclude` command.

### 18.2.11. Auto advance to next statement

If this option is enabled, then the cursor will automatically jump to the next statement in the script, when you execute a single statement using **Ctrl-Enter** ("Run current statement"). This can also be toggled through the menu `SQL » Auto advance to next`

For more information on how you can execute statements in the editor, please refer to [Executing Statements](#)

### 18.2.12. Highlight current statement

When running several statements (e.g. by using "Execute all") this option will highlight the current statement. The editor will be scrolled to make sure the currently executed statement is visible.

### 18.2.13. Retain current statement highlight

If "Highlight current statement" is enabled and this option is turned on, the highlighting will be kept once execution has finished.

### 18.2.14. Allow editing while executing

When running a statement, the editor is set to read-only in order to allow a consistent statement highlighting. When this option is turned on, the text in the editor may be modified even if a statement is running. If the text in the editor is modified during execution, statement and error highlighting will not be done any more.

### 18.2.15. Right click moves cursor

Normally a right click in the SQL editor does not change the location of the cursor (caret). If this option is checked, then a right click will also change the caret's location (to where the mouse cursor is located)

### 18.2.16. Current directory follows active file

If this option is enabled, the file open dialog will default to the directory of the current file in the editor. If no file is loaded in the editor, the directory that is defined through the "Default directory" option will be selected.

## 18.3. Editor colors

### 18.3.1. Current line color

If you want to highlight the line in which the cursor is located, specify the color for the highlighting. To disable the highlight for the current line, simply "remove" the color selection by clicking on the remove button.

### 18.3.2. Selected text

The color that is used to highlight selected text.

### 18.3.3. Error highlight color

When a statement is not executed correctly (and the DBMS signals an error) it is highlighted in the editor. With this option you can select the color that is used to highlight the incorrect statement.

### 18.3.4. Syntax highlighting colors

You can change the colors for the different types of keywords in the editor.

## 18.4. Font settings

### 18.4.1. Editor font

The font that is used in the SQL editor. This font is also used when displaying the SQL source for tables and other database objects in the [DbExplorer](#).

### 18.4.2. Data font

The font that is used to display result sets. This includes the object list and results in the [DbExplorer](#).

### 18.4.3. Message font

The font that is used in the message pane of the SQL window.

### 18.4.4. Standard font

The standard font that is used for menus, labels, buttons etc.

## 18.5. Auto-completion options

### 18.5.1. Paste completion in

With this option you can select how the selected object name from the code completion popup is pasted into the editor. `As is` means, that the values will be inserted into the editor as it was retrieved from the database. This option will also be used when SQL statements are generated internally (e.g. for updating the result set or when you export/copy data as SQL statements)

### 18.5.2. Sort pasted columns by

When selecting to paste all (or several columns) from the popup window, you can select with this option, in which order the columns should be written into the editor.

### 18.5.3. Close completion with search

When using the quicksearch feature in the [code completion](#) this option controls the behaviour when hitting the ESC key. If this option is enabled, the ESC key will also close the popup window with the available choices. If this option is disabled, the ESC key will only close the quicksearch *input* field.

#### 18.5.4. Sort entries in popup

If this is enabled, columns are sorted alphabetically in the popup. If not, they are listed in the order as they are returned by the database.

#### 18.5.5. Quick search matches anywhere

If this option is enabled, the typed characters match anywhere in the object name. If this option is disabled, the object name must start with the entered search value.

#### 18.5.6. Filter by quicksearch

When this option is enabled, only those entries are shown in the popup that match the entered values in the quick search.

### 18.6. Workspace options

#### 18.6.1. Auto-Save workspace

If this option is enabled, the current workspace is saved each time you run a SQL statement.

#### 18.6.2. Create workspace backup

If this option is enabled the current workspace file will be backed up, before saving the new workspace. You can keep multiple versions of the workspace by supplying a number in the "Max. Backups" input field. If a value  $> 1$  is entered, saving the workspace will create a new "version" of the backup file. The versions will have the version number appended (e.g. `testdata.wksp.1`, `testdata.wksp.2` and so on). The most recent version is the one with the highest number.

#### 18.6.3. Workspace backup directory

By default the backups for the workspaces are stored in the same directory as the workspace file itself. If you want to keep the (versioned) backups in a separate directory, you can specify it here.

If you specify a relative directory, it will be relative to the [config directory](#).

#### 18.6.4. Remember open files in workspace

You can customize how external files (that have been loaded using File » Open) are remembered in the workspace. You can select three different options:

Content and filename	When this option is selected, the filename that is loaded in the editor tab will be stored in the workspace. The next time the workspace is loaded the file is opened as well. This is the default setting
Content only	When this option is selected, only the content of the editor tab is saved (just like any other editor tab), but the link to the filename is removed. The next time the workspace is loaded, the file will <b>not</b> be opened.
Nothing	Neither the content, nor the filename will be saved. The next time the workspace is loaded, the editor tab will be empty.

## 18.7. Options for displaying data

### 18.7.1. Sort Locale

When you sort the result set, characters values will be sorted case-sensitiv by default. This is caused by the `compareTo()` method available in the Java environment which puts lower case characters in front of upper case characters when sorting. With the "Sort Locale" option you can select which language rules should be applied while sorting. Note that sorting with a locale is slower than using the "Default" setting.

### 18.7.2. Show selection summary in statusbar

If this option is enabled the number of selected rows in the result will be displayed in the status bar.

If you have a single numeric column selected (by holding down the **Alt** key while selecting with the mouse), the statusbar will display the sum of the selected values.

### 18.7.3. Displaying multi-line values

SQL Workbench/J uses a special renderer for the contents of CLOB columns that is capable of displaying multiple lines (i.e. honors newlines and linefeeds in the data retrieved from the database).

This multi-line renderer is usually not applied for VARCHAR columns. If your database stores text in VARCHAR columns that contains line breaks, you can define a threshold for the length of the column. Any column that is defined with a higher value will be displayed with a multiline renderer.

The default value of 250 means that a `VARCHAR(250)` column will be displayed with the multiline renderer. A `VARCHAR(210)` will be displayed in a single line.

Using the multiline renderer has some minor drawbacks when editing the data, and is a bit slower when displaying large result sets.

The feature [Adjust row height](#) only works with multi-line fields.

### 18.7.4. Column width settings

#### Automatically adjust column widths

If this option is enabled, the widths of the result set columns are automatically adjusted to fit the largest value (respecting the min. and max. size settings) after retrieving data. Note that you can manually optimize the column widths using View » Optimize width for all columns.

#### Adjust to column headers

When calculating the optimal width for a column (either manually or if "Auto adjust column widths" is enabled, then the column's label will be included in the width calculation if this option is enabled. If this option is disabled, and the column contains very short values, the column width could be smaller than the column's label.

This option is also used when manually optimizing the column width,

#### Max. column width

When the initial display size of a column is calculated, or if you optimize the column widths to fit the actual data, columns will not exceed this width. This is useful when displaying large character columns.

## Min. column width

When the initial display size of a column is calculated, or if you optimize the column widths to fit the actual data, columns will not exceed this width.

### 18.7.5. Row height settings

#### Automatically adjust row height

If this option is enabled, the height of each column is automatically adjusted after data retrieval to display as many lines of the column values (for character columns) as possible. Note that you can manually optimize the row height using View » Optimize row height.

Not every (character) column is displayed in a manner that multiple lines will be displayed. The default setting is to always display CLOB columns as multiline. VARCHAR (and CHAR) columns will only be displayed in multiline mode if they can hold more than 250 characters. This limit can be [changed](#).

#### Allow row height resizing

If this option is enabled, you can manually adjust the height of each row using the mouse. This option does not need to be enabled in order to (automatically) optimize the row height.

#### Max. number of lines

When calculating the optimal height for each row, the number of lines defined with this option will never be exceeded.

### 18.7.6. Alternate row colors

If this option is selected, the rows in the data table will be displayed with alternating background color. You can choose the alternate color (the other color is defined by the used [Look & Feel](#)) with the font chooser next to the checkbox.

### 18.7.7. Color for NULL values

If a color is defined, NULL values will be highlighted with the selected colors in the result set.

## 18.8. Options for formatting data

### 18.8.1. Date, timestamp and time formats

Define the format for displaying date, date/time (timestamp) and time columns in the result set. For details on the format of this option, please refer to the documentation of the [SimpleDateFormat](#) class. This format is also used when parsing input for date or timestamp fields, so if you enter a date while [editing](#) the data, make sure you enter it the same way as defined with this option.

Here is an overview of the letters and their meaning that can be used to format the date and timestamp values. Be aware that case matters!

Letter	Description
G	Era designator (Text, e.g. AD)
y	Year (Number)

Letter	Description
M	Month in year (Number)
w	Week in year (Number)
W	Week in month (Number)
D	Day in year (Number)
d	Day in month (Number)
F	Day of week in month (Number)
E	Day in week (Text)
a	AM/PM marker
H	Hour in day (0-23)
k	Hour in day (1-24)
K	Hour in am/pm (0-11)
h	Hour in am/pm (1-12)
m	Minute in hour
s	Second in minute
S	Milliseconds
z	General time zone (e.g. Pacific Standard Time; PST; GMT-08:00)
Z	RFC 822 time zone (e.g. -0800)

### 18.8.2. Oracle DATE as TIMESTAMP

The Oracle DATE datatype includes the time as well. But the JDBC driver does not retrieve the time part of a DATE column, so when retrieving DATE values, this would remove the time stored in the database. If this option is enabled, SQL Workbench/J will treat Oracle's DATE columns as TIMESTAMP columns, thus preserving the time information.

### 18.8.3. Decimal symbol

The character which is used as the decimal separator when displaying numbers.

### 18.8.4. Decimal digits

Define the maximum number of digits which will be displayed for numeric columns. This only affects the display of the number internally they are still stored as the DBMS returned them. To see the internal value, leave the mouse cursor over the cell. The tooltip which is displayed will contain the number as it was returned by the JDBC driver. When exporting data or copying it to the clipboard, the real value will be used.

## 18.9. Options for data editing

### 18.9.1. Confirm result set updates

When this option is enabled, the statements which are sent to the database when saving changes to result set table, are displayed before execution. The update can be cancelled at that point if the statements are not correct. The generated statements can also be saved to a file from that window.

The statement(s) that are displayed in the confirmation window can not be changed!

### 18.9.2. Confirm discarding changed results

When running a statement that would replace a result that has changes that are not saved to the database, you will be prompted whether you want to cancel the current operation that would discard those changes.

This applies to statements run in the editor, as well as to changes done in the [Data tab of the DbExplorer](#).

You will not be prompted when running statements in the editor, when the option [Append results](#) is enabled.

### 18.9.3. Highlight required fields

When editing data either in the result set or in the data tab of the DbExplorer, fields that are set to NOT NULL in the underlying table, will be displayed with a different background color if this option is selected.

### 18.9.4. Color for required fields

If required fields are highlighted during editing, this option defines the background color that is used.

### 18.9.5. Default PK Map

This property defines a mapping file for primary key columns. The information from that file is read whenever the primary keys for a table cannot be obtained from the database. For a detailed description on how to define extra primary key columns, please refer to the [WbDefinePk](#) command.

### 18.9.6. Single record dialog

When displaying data in the Single record dialog you can customize the width for the input fields, and the default height for [multiline](#) columns.

## 18.10. DbExplorer options

### 18.10.1. DB Explorer as Tab

The Database Explorer can either be displayed as a separate window or inside the main window as another tab. If this option is selected, the Db Explorer will be displayed inside the main window. If the option Retrieve DB Explorer is checked as well, the current database scheme will be retrieved upon starting SQL Workbench/J

### 18.10.2. Automatically retrieve objects

If this option is enabled, the contents of the database schema is retrieved when the DB Explorer is displayed. If this option is not checked, either the Refresh button or selecting a schema or table type will load the list.

### 18.10.3. Show trigger panel

By default triggers are shown only in the details of a table. If the option "Show trigger panel" is selected, an additional panel will be displayed in the DbExplorer that displays all triggers in the database independently of their table.

### 18.10.4. Focus to data panel

When this option is selected, the focus inside the DbExplorer will be set to the data panel, after an object in the list has been selected (and the data panel is visible).

### 18.10.5. Show focus

When this option is selected, a rectangle indicating the currently focused panel will be displayed, to indicate the component that will receive keystrokes e.g. shortcuts such as `Ctrl-R`.

### 18.10.6. Generate PK constraint name

When displaying the SQL source for a table, a name will be generated for primary key constraint if the current constraint has no name or a system generated name.

System generated names are identified using a regular expression that can be [configured](#).

If this option is selected, the generated SQL will not reflect the real statement that was used to create the table!

### 18.10.7. Remember object type

The list of objects can be filtered with the dropdown. If the option "Remember object type" is selected, the current object type will be stored in the workspace of the current connection, and will be restored the next time.

### 18.10.8. Remember sort column

When this option is selected, the sort column in the data display of the DbExplorer will be restored after reloading the table data.

### 18.10.9. Remember column order

When you [reorder](#) the column in the data display of a table, enabling this option will automatically store the new column order and apply it the next time the table data is displayed.

### 18.10.10. Default object type

If "Remember object type" is not enabled, you can define a default object type that is selected in the dropdown when the DbExplorer is displayed initially.

### 18.10.11. Object details tabs

With this dropdown you can select the position of the details tabs (Columns, Source, Data etc).

## 18.11. Window Title

The title bar of the main window displays information about the current connection, workspace and editor file. Some of these elements can be enabled or disabled with the options on this page.

### 18.11.1. Application name at end

If this option is enabled, the Application name will be put at the end of the window title.

### 18.11.2. Show Workspace name

If this option is enabled, the currently loaded workspace name will be displayed in the main window's title.

### 18.11.3. Show Profile Group

If this option is enabled, the group of the current connection profile will be displayed in the main window's title. The name of the current connection profile will always be shown.

### 18.11.4. Enclose Group With

If you select to display the current profile's group, you can select a pair of characters to put around the group name.

### 18.11.5. Separator

If you select to display the current profile's name and group, you can select the character that separates the two names.

### 18.11.6. Editor Filename

If the current editor tab contains an external file, you can choose if and which information about the file should be displayed in the window title. You can display nothing, only the filename or the full path information about the current file. The information will be displayed behind the current profile and workspace name.

## 18.12. SQL Formatting

These options influence the behaviour of the SQL Formatter when [reformatting](#) a SQL statement in the editor.

### 18.12.1. Max. length for sub-select

When the SQL formatter hits a sub-SELECT while parsing it will not reformat any statement which is shorter then the length specified with this option, i.e. any sub-SELECT shorter then this value will be formatted as one single statement without line breaks or indentation. See SQL Formatter for details on how the SQL formatting works.

### 18.12.2. Columns in SELECT

This property defines the number of columns the formatter puts in on line when formatting a `SELECT` statement. The default of 1 (one) will put each column into a separate line:

```
SELECT p.name,
       p.firstname,
       a.city,
       a.zip
FROM person p JOIN address a ON (p.person_id = a.person_id);
```

If this is set to 2, this would result in the following formatted `SELECT`:

```
SELECT p.name, p.firstname,
       a.city, a.zip
FROM person p JOIN address a ON (p.person_id = a.person_id);
```

The above example would list all columns in a single line, if this option is set to 4 (or a higher value):

```
SELECT p.name, p.firstname, a.city, a.zip
FROM person p JOIN address a ON (p.person_id = a.person_id);
```

### 18.12.3. Columns in INSERT

This property defines the number of columns the formatter puts in on line when formatting an INSERT statement. A value of one will list each column in a separate line in the INSERT part and the VALUES part

```
INSERT INTO PERSON
(
    id,
    firstname,
    lastname
)
VALUES
(
    42,
    'Arthur',
    'Dent'
);
```

When setting this value to 2, the above example would be formatted as follows:

```
INSERT INTO PERSON
    (id, firstname,
      lastname)
VALUES
    (42, 'Arthur',
      'Dent');
```

### 18.12.4. Columns in UPDATE

This property defines the number of columns the formatter puts in on line when formatting an UPDATE statement. A value of 1 (one) will put each column into a separate line:

```
UPDATE person
    SET firstname = 'Arthur',
        lastname = 'Dent'
WHERE id = 42;
```

With a value of 2, the above example would be formatted as follows:

```
UPDATE person
    SET firstname = 'Arthur', lastname = 'Dent'
WHERE id = 42;
```

### 18.12.5. Quoted elements per line

This option is used when changing the selected text into elements suitable for an IN list using [SQL » Create SQL List](#). The number of values that are kept on a single line is controlled with this option.

### 18.12.6. Other elements per line

This option defines how many values will be put into a single line when creating non-quoted elements ([Create non-char SQL List](#)).

### 18.12.7. Lowercase functions

If this option is selected, standard ANSI functions will converted to lowercase when formatting a SQL statement.

### 18.12.8. Uppercase keywords

If this option is selected, standard ANSI keywords (`SELECT`, `UPDATE`) will converted to uppercase when formatting a SQL statement, otherwise they will be converted to lowercase.

## 18.13. SQL Generation

### 18.13.1. Generated UPDATE statements

If formatting of `UPDATE` statements is enabled, the threshold defines how many columns have to be present for a single `UPDATE` statement in order to put each column into a separate line. If the number of columns is lower then this value they will remain on one line. The keywords (`UPDATE`, `WHERE`) will still be formatted into new lines.

### 18.13.2. Generated INSERT statements

If formatting of `INSERT` is enabled, the way they are formatted can be controlled with several values.

#### Column threshold

If the number of columns in the statement exceeds this value, the columns will be spread over several lines. The number of columns that are put into each line is controlled using the option "Columns per line".

#### Columns per line

If the number of columns in the option "Column threshold" is exceeded, this option controls how many columns are put into each line

### 18.13.3. Include owner in export

This setting controls whether SQL Workbench/J uses the owner (schema) when creating SQL scripts during exporting data (through `WbExport` or "Save as"). When this option is selected, the usage of the schema depends on the [ignore schema](#) setting that controls ignoring certain schemas for specific DBMS. When this option is not selected, the schema/owner will never be used for SQL scripts.

### 18.13.4. Date literals for clipboard

Defines the date literal format to be used when copying data as SQL statements *to the clipboard*. For a detailed description of the different formats please refer to the [WbExport](#) description. This option does not influence the default format used by the `WbExport` command.

When you copy data as "Text" (tab-separated) to the clipboard, the date and timestamp format from the [general options](#) is used.

### 18.13.5. Date literals for WbExport

Defines the date literal format to be used for the [WbExport](#) command. The value of this option is used if the `-sqlDateLiterals` switch is not supplied when running `WbExport`. This default value is reported when `WbExport` is executed without parameters.

### 18.13.6. Date literals for WbDataDiff

Defines the date literal format to be used for the [WbDataDiff](#) command. The value of this option is used if the `-sqlDateLiterals` switch is not supplied when running `WbDataDiff`. This default value is reported when `WbDataDiff` is executed without parameters.

## 18.14. External tools

On this page, you can define external tools (programs). Currently the only place where this is used, is in the [BLOB info dialog](#), to open the BLOB data with one of the defined external tools.

This could be a program to display images, [OpenOffice](#) to display office documents or a text editor to display text files.

You do not need to define the PDF Reader here, as the definition from the [general options](#) will automatically be used in the BLOB info dialog.

## 18.15. Look and Feel

If you want to use additional Look and Feels that are not part of the JDK, you can specify them here.

A Look And Feel definition consists of a name, the class name to be used and the location of the JAR file that provides the look and feel implementation. The class name that has to be used should be available in the documentation of the look and feel of your choice. The name is SQL Workbench/J internal and is only used when displaying the list of available Look and Feels.

The current look and feel is only changed when you click on the Make current button. Simply selecting a different entry in the list on the left side will **not** change the look and feel.

When you switch the current Look & Feel, you will need to restart the application to activate the new look and feel. Note that if you switch the current Look & Feel it will be changed, regardless whether you close the options dialog using Cancel or OK.

## 19. Configuring keyboard shortcuts

You can configure the keyboard shortcut to execute a specific action (=menu item) in the dialog which is displayed when you select Tools » Configure shortcuts.... The dialog lists the available actions together with their configured shortcut and their default shortcut.

### 19.1. Assign a shortcut to an action

To assign a (new) keyboard combination for a specific action, select (highlight) the action in the list and click on the Assign button. A small window will pop up, where you can press the key combination which you would like to assign to that action. Note that only F-Keys (F1, F2, ...) can be used without a modifier (Shift, Control, Alt). All other keys need be pressed together with one of the modifier keys.

After you have entered the desired keyboard shortcut, press the OK button. If the shortcut is already assigned to a different action, you will be prompted, if you want to override that definition. If you select to overwrite the shortcut for the other action, that action will then have **no** shortcut assigned

### 19.2. Removing a shortcut from an action

To remove a shortcut completely from an action, select (highlight) that action, and click on the Clear button. Once the shortcut has been cleared, the action is no longer accessible through a shortcut (only through the menu).

### 19.3. Reset to defaults

If you want to reset the shortcut for a single action to its default, select (highlight) the action in the list, and click on the Reset button. To reset all shortcuts click on the Reset all button.

## 20. Advanced configuration options

This section describes the additional options for SQL Workbench/J which are not (yet) available in the options dialog.

The name of the setting refers to the entry in the file `workbench.settings` which is located in the [configuration directory](#). Not all listed properties will be present in `workbench.settings`. In this case, simply create a new line with the property name and the value as described here. The position where you add this entry does not matter.

Every property can also be specified on the commandline when starting SQL Workbench/J by setting a system property with that name using the `-Dworkbench.property=value` switch. When using one of the Windows launchers (.exe) you have to use `-J-Dworkbench.property=value`. See the section about [Java options](#) in the description of the Windows launcher.

### 20.1. Database Identifier

Some parameters are used such that a list of "Database Identifiers" is expected. The identifier that needs to be put there can be obtained by hovering the mouse over the connection URL information in the main window, or from the log file. After a successful connect to a database, there will be an entry in the log file similar to this:

```
INFO 15.08.2004 10:24:42 Connected to: [HSQL Database Engine]
```

If the description for a property in this chapter refers to a "Database Identifier", the text between (but not including) the square brackets has to be used.

### 20.2. DBID

For some settings, where the ID is part of the property's key, a "clean" version of the Database Identifier, called the DBID, is used. This DBID is displayed in the connection info dialog (right click on the connection URL in the main window, then choose "Connection Info").

The DBID is also reported in the log file:

```
INFO 15.08.2004 10:24:42 Using DBID=hsqldb_database_engine
```

If the description for a property in this chapter refers to the "DBID", then this value has to be used.

If the DBID is part of a property key this will be referred to as `[dbid]` in this chapter.

### 20.3. GUI related settings

#### Showing accelerator in menu

Property: `workbench.gui.showmnemonics`

Possible values: `true`, `false`

Usually the mnemonic (aka. Accelerator) for a menu item is not shown under Windows 2000 or later. It will only be shown, when you press the ALT key. With this settings, this JDK behaviour can be controlled.

Default: `true`

#### Controlling the type of print dialog

Property: `workbench.print.nativepagedialog`

Possible values: `true`, `false`

When printing the contents of a table, this settings controls the type of print dialog to be used. The default setting will open the native print dialog of the operating system. If you experience problems when trying to print, set this property to `false`. SQL Workbench/J will then open a cross-platform print dialog.

Default value: `true`

## 20.4. Editor related settings

### Include Oracle public synonyms in auto-completion of tables

Property: `workbench.editor.autocompletion.oracle.public_synonyms`

Possible values: `true`, `false`

When using auto completion for table columns and table names, Oracle's public synonyms are not included by default. This has two reasons: first, the author believes that public synonyms shouldn't be used (it's just as bad as global variables in programming) and second, Oracle defines a huge number of public synonyms that would make the popup with all available tables very long and hard to use. Setting this property to `true`, will include public synonyms in the popup. Please refer to [filtering synonyms](#) for details on how to filter out unwanted synonyms from this list.

Default value: `false`

### Set the modifier key for rectangular selections in the editor

Property: `workbench.editor.rectselection.modifier`

These properties control the modifier key that needs to be pressed to enable rectangular selections in the editor. Possible values are `alt` for setting the **Alt** key as the modifier, or `ctrl` for setting the **Ctrl** key as the modifier.

Default value: `alt`

### Default file encoding

Property: `workbench.file.encoding`

Several internal commands use an encoding when writing external text files (e.g. [WbExport](#)). If no encoding is specified for those commands, the default platform encoding as reported by the Java runtime system is used. You can overwrite the default encoding that Java assumes by setting this property.

Default value: empty, the Java runtime default is used

### Limiting size of the text put into the history

Property: `workbench.sql.history.maxtextlength`

When you execute a SQL statement in the editor, the current content of the editor is put into the history buffer. If you are editing large scripts, this can lead to memory problems. This property controls the max. size of the editor text that is put into the history.

If the current editor text is bigger than the size defined in this property the text is not put into the history.

Default value: 10485760 (10MB)

## Controlling newlines in code snippets

Property: `workbench.clipcreate.includenewline`

Possible values: `true`, `false`

When creating a [Java code snippet](#), the newlines inside the editor are preserved by putting a `\n` character into the String declaration. Setting this property to `false`, will tell SQL Workbench/J not put any `\n` characters into the Java string.

Default: `true`

## Controlling the concatenation character for code snippets

Property: `workbench.clipcreate.concat`

When creating a [Java code snippet](#), each line is concatenated using the standard `+` operator. If your programming language uses a different concatenation character (e.g. `&`), this can be changed with this property.

Default: `+`

## Controlling the prefix for code snippets

Property: `workbench.clipcreate.codeprefix`

When creating a [Java code snippet](#), this is prefixed with `String sql =`. With this property you can adjust this prefix.

Default: `String sql =`

# 20.5. DbExplorer Settings

## Controlling data display in the DbExplorer

Property: `workbench.db.objecttype.selectable.\[dbidl\]=value1,value2,...`

The DbExplorer makes the "data" tab available based on the type of the selected object in the object list (second column). If the type returned by the JDBC driver is one of the types listed in this property, SQL Workbench/J assumes that it can issue a `SELECT * FROM` to retrieve data from that object.

Default values:

```
.defaultt=view,table,system view,system table
.postgresql=view,table,system view,system table,sequence
.rdb=view,table,system,system view
```

The values in this property are not case-sensitive (TABLE is the same as table)

## Customizing the SELECT to be used for the data tab

You can customize the generated SELECT that is used to display the table data depending on the column type. Please refer to the [DbExplorer chapter](#) for details.

## Customizing columns that can be searched

Property: `workbench.db.\[dbidl\].datatypes.searchable`

[DbExplorer's "Search table data"](#) feature only includes columns with the datatypes CHAR and VARCHAR into the WHERE clause for searching.

Some database systems allow CLOB columns to be searched using a LIKE expression as well. This property can be used to list all datatypes that can be used in a LIKE condition.

Default values:

For PostgreSQL: text

For MySQL: longtext, tinytext, mediumtext

## Microsoft SQL Server extended property for remarks

Property: `workbench.db.microsoft_sql_server.remarks.propertyname`

Defines the name of the extended property that is queried in order to retrieve table or column remarks for SQL Server.

SQL Workbench/J will use the table function [fn\\_listextendedproperty](#) to retrieve the extended property defined by this configuration setting to retrieve remarks.

Default value: MS\_DESCRIPTION

## Displaying table comments for MySQL

Property: `workbench.db.mysql.tablecomments.retrieve`

By default the MySQL JDBC driver does not return comments defined on tables. If you use table comments, you can enable their display by setting this property to true. This might also show comments generated by MsSQL itself.

Default value: false

## Retrieving remarks for Microsoft SQL Server

Property:

`workbench.db.microsoft_sql_server.remarks.object.retrieve`  
`workbench.db.microsoft_sql_server.remarks.column.retrieve`

Enables/disables the retrieval of extended properties as a replacement for the standard SQL COMMENT ON ... capability.

SQL Workbench/J will use SQL Server's [fn\\_listextendedproperty](#) table function to retrieve table or column remarks. As this can have a performance impact on the retrieval of tables or columns, this retrieval can be disabled using this configuration setting.

Default value: true for both properties

## 20.6. Database related settings

### Automatically connect the DataPumper

Property: `workbench.datapumper.autoconnect`

When opening the [DataPumper](#) it will connect to the current profile as the source connection. If you do not want the DataPumper to connect automatically set this property to false

Default: `true`

### Controlling COMMIT for DDL statements

Property `workbench.db.[dbid].ddlneedscommit`

Possible values: `true`, `false`

Defines if the DBMS supports transactional DDL (CREATE TABLE, DROP TABLE, ...)

Default: `false`

### COMMIT/ROLLBACK behaviour

Property: `workbench.db.[dbid].usejdbccommit`

Possible values: `true`, `false`

Some DBMS return an error when COMMIT or ROLLBACK is sent as a regular command through the JDBC interface. If the DBMS is listed here, the JDBC functions `commit()` or `rollback()` will be used instead.

Default: `false`

### Generating constraints for SQL source

Property: `workbench.db.inlineconstraints`

This setting controls the generation of the CREATE TABLE source in the [DbExplorer](#). This is a comma separated list of [Database Identifiers](#) that only support defining primary and foreign keys inside the CREATE TABLE statement.

If a DBMS is not listed here, the table constraints will be re-created using ALTER TABLE.

Default: `FirstSQL/J`

### Case sensitivity when comparing values

Property `workbench.db.[dbid].casesensitive`

Possible values: `true`, `false`

The search panel of the DbExplorer highlights matching values in the result tables. The highlighter needs to know whether string comparisons in the database are case sensitive in order to highlight the correct values.

Default: `false`

### Defining SQL commands that may change the database

Property: `workbench.db.updatingcommands` for general SQL statements

Property: `workbench.db.[dbid].updatingcommands` for DBMS specific update statements

When enabling the [read only](#) or [confirm update](#) option in a connection profile, SQL Workbench/J assumes a default set of SQL commands that will change the database. With this property you can add additional keywords that should be considered as "updating commands". This is a comma separated list of keywords. The keywords may not contain whitespace.

No default

## Database switch in DbExplorer

Property: `workbench.dbexplorer.switchcatalog`

When connected to a DBMS that supports multiple databases (catalogs) for the same connection, the DbExplorer displays a dropdown list with the available databases. Switching the selected catalog in the dropdown will trigger a switch of the current catalog/database if the DbExplorer uses its [own connection](#). If you do not want to switch the database, but merely apply the new selection as a filter (which is always done, if the DbExplorer shares the connection with the other SQL panels) set this property to `false`.

Default: `true`

## Filtering tables

Property: `workbench.db.\[dbid\].exclude.tables`

Whenever SQL Workbench/J retrieves a list of tables (e.g. the DbExplorer, auto completion, [WbSchemaReport](#)) certain tables can be filtered out by supplying a regular expression in this property. The default setting will filter Oracle tables that reside in the "Recycle bin". This setting can be applied on a per DBMS basis

Default value: `workbench.db.oracle.exclude.tables=^BIN\\$.*`

Note that you need to use two backslashes in the RegeEx.

## URL for online manual

Property: `workbench.db.\[dbid\].manual`

This defines the URL of the online manual for that DBMS. This URL is shown in the browser when using the menu item: Help » DBMS Manual will display the

## Filtering synonyms

Property: `workbench.db.\[dbid\].exclude.synonyms`

The [database explorer](#) and the [auto completion](#) can display (Oracle public) synonyms. Some of these are usually not of interest to the end user. Therefore the list of displayed synonyms can be controlled. This property defines a regular expression. Each synonym that matches this regular expression, will be excluded from the list presented in the GUI.

Default value (for Oracle): `^AQ\\$. *|^MGMT\\$. *|^GV\\$. *|^EXF\\$. *|^KU\\$. *|^WM\\$. *|^MRV_. *|^CWM_. *|^CWM2_. *|^WK\\$. *|^CTX_. *`

Note that you need to use two backslashes in the RegeEx.

## Support for Oracle materialized views (snapshots)

Property: `workbench.db.oracle.detectsnapshots`

When displaying the list of tables in the [database explorer](#) Oracle materialized views (snapshots) are identified as tables by the Oracle JDBC driver. To identify a specific "table" as a materialized view, a second request to the database is necessary (accessing the system view ALL\_MVIEWS). As this request can slow down the retrieval performance, this feature can be turned off. If for any reason the ALL\_MVIEWS view cannot be accessed, this feature will be turned off until you re-connect to the database.

Default value: `true`

### Fix type display for VARCHAR columns in Oracle

Property: `workbench.db.oracle.fixcharsemantics`

The Oracle driver does not report the size of VARCHAR2 columns correctly if the character semantic has been set to "char". The JDBC driver always returns the length in bytes. When this property is set to `true`, the length for those columns will be displayed correctly in the DbExplorer. As this means SQL Workbench/J is using its own query to retrieve the table definition, this might not always yield the same results as the original statement from the Oracle driver. If your table definitions are not displayed correctly, set this value to `false` so that the original driver methods are used. The statement used by SQL Workbench/J is a bit faster than the original Oracle statement, as it does not use a `LIKE` predicate (which is required to comply with the JDBC specs).

Default value: `true`

### Fix type display for NVARCHAR2 columns in Oracle

Property: `workbench.db.oracle.fixnvarchartype`

The Oracle driver does not report the type of NVARCHAR2 columns correctly. They are returned as `Types.OTHER`. If this property is enabled, then SQL Workbench/J is also using its own `SELECT` statement to retrieve the table definition.

Default value: `true`

### Defining a base directory for JDBC libraries

Property: `workbench.libdir`

A directory that contains the .jar files for the [JDBC drivers](#). The value of this property can be referenced using `%LibDir%` in the driver's definition. The value for this can also be specified [on the commandline](#).

No default

### Defining keywords for date or timestamp input

Property: `workbench.db.keyword.current_date`

The "literals" that are accepted for DATE columns to identify the current date. Default values are `current_date`, `today`

Property: `workbench.db.keyword.current_timestamp`

The "literals" that are accepted for TIMESTAMP columns to identify the current date/time. Default values are `current_timestamp`, `sysdate`, `systimestamp`

Property: `workbench.db.keyword.current_time`

The "literals" that are accepted for TIME columns to identify the current time. Default values are `current_time`, `now`

### Use Savepoints to guard DML statement execution

Property: `workbench.db.\[dbid\].sql.usesavepoint`

Possible values: `true`, `false`

Some DBMS (such as PostgreSQL) cannot continue inside a transaction when an error occurs. A script with multiple DML statements can therefore not run completely if one statement fails, even if you choose to ignore the error. If this property is set to `true`, SQL Workbench/J will set a savepoint before executing a DML statement (`SELECT`, `INSERT`). In case of an error the savepoint will be rolled back and the transaction can continue.

Default value: `false`

### Use Savepoints to guard DDL statement execution

Property: `workbench.db.[dbid].ddl.usesavepoint`

Possible values: `true`, `false`

Some DBMS (such as PostgreSQL) cannot continue inside a transaction when an error occurs. A script with multiple DDL statements can therefore not run completely if one statement fails, even if you choose to ignore the error. If this property is set to `true`, SQL Workbench/J will set a savepoint before executing a DDL statement. In case of an error the savepoint will be rolled back and the transaction can continue.

Default value: `false`

### Use Savepoints for update/insert mode for WbImport

Property: `workbench.db.[dbid].import.usesavepoint`

Possible values: `true`, `false`

Some DBMS (such as PostgreSQL) cannot continue inside a transaction when an error occurs. When running WbImport in `update`, `insert` or `insert, update` mode, the first of the two statements needs to be rolled back in order to be able to continue the import. If this property is set to `true`, SQL Workbench/J will set a savepoint before executing the first (insert or update) statement. In case of an error the savepoint will be rolled back and WbImport will try to execute the second statement.

Default value: `false`

### Ignore errors during data retrieval

Property: `workbench.db.ignore.readerror`

Possible values: `true`, `false`

When retrieving data (e.g. using a `SELECT` statement) errors that are reported by the driver will be displayed to the user. The retrieval will be terminated. If you want to ignore errors and replace the data that could not be retrieved with a `NULL` value, set this property to `true`.

Using this parameter is not recommended as it might produce results that do not reflect the data as it is stored in the database.

Default value: `false`

### Customizing data type mapping

Property: `workbench.db.[dbid].typemap`

When using the `-createTarget` parameter for [WbCopy](#), the type mapping from the JDBC driver might not be sufficient or correct. With this setting you can define your own type mapping for a specific dbms. The entry is a list of mappings that map the numeric value of a JDBC datatype (as defined in [java.sql.Types](#)) to a real data type name for the DBMS. The numeric JDBC datatype value and the DBMS specific datatype name are separated with a colon. Each pair is separated by a semicolon.

The following entry maps the JDBC datatype with the value 3 (NUMERIC) to the target datatype `double` and the value 2 (BIGINT) to the target type `NUMBER`. The `NUMBER` datatypes needs uses two parameter placeholders `$size` and `$digits`. The last mapping maps the JDBC value -1 (LONGVARCHAR) to the DBMS type `VARCHAR` using only the `$size` parameter

```
workbench.db.[some_db].typemap=3:DOUBLE;2:NUMBER($size,$digits);-1:VARCHAR($size)
```

JDBC 4.0 defines the following constants:

- `BIGINT` = -5
- `BINARY` = -2
- `BIT` = -7
- `BLOB` = 2004
- `BOOLEAN` = 16
- `CHAR` = 1
- `NCHAR` = -15
- `CLOB` = 2005
- `NCLOB` = 2011
- `DATE` = 91
- `DECIMAL` = 3
- `DOUBLE` = 8
- `FLOAT` = 6
- `INTEGER` = 4
- `LONGVARBINARY` = -4
- `LONGVARCHAR` = -1
- `LONGNVARCHAR` = -16
- `NUMERIC` = 2
- `REAL` = 7
- `SMALLINT` = 5
- `TIME` = 92
- `TIMESTAMP` = 93
- `TINYINT` = -6
- `VARBINARY` = -3
- `VARCHAR` = 12
- `NVARCHAR` = -9
- `ROWID` = -8
- `SQLXML` = 2009

## 20.7. SQL Execution related settings

### Maximum script size for in-memory script execution

Property: `workbench.sql.script.inmemory.maxsize`

This setting controls the size up to which files that are executed in batch mode or via the [WbInclude](#) command are read into memory. Files exceeding this size are not read into memory but processed statement by statement. When a file is not read into memory the automatic detection of the [alternate delimiter](#) does not work any longer. The size is given in bytes.

Default: 1048576

### Ignoring certain SQL commands

Property: `workbench.db.ignore.\[dbidl\]`

For a DBMS identifier you can define a list of commands that are simply ignored by SQL Workbench/J. This is useful e.g. for Oracle, when you want to run scripts that are intended for SQL\*Plus. If those scripts contain special SQL\*Plus commands (that are not understood by the Oracle server as SQL\*Plus executes these commands directly) they would fail in SQL Workbench/J. If those commands are simply ignored and not send to the server, the scripts can run without modification.

Default: `workbench.db.ignore.oracle=prompt,exit,whenever`

### Enabling short WbInclude

Property: `workbench.db.supportshortinclude`

By default the [WbInclude](#) command can be shortened using the @ sign. This behaviour is disabled for MS SQL to avoid conflicts with parameter definitions in stored procedures. This property contains a list of [DBIDs](#) for which this should be enabled. To enable this for all DBMS, simply use \* as the value for this property.

Default: `oracle, rdb, hsqldb, postgresql, mysql, adaptive_server_anywhere, cloudscape, apache_derby`

### Check for single line commands without delimiter

Property: `workbench.db.checksinglelinecmd`

When parsing a SQL script, SQL Workbench/J supports statements that are put into a single line without a delimiter. This is primarily intended for compatibility with Oracle's SQL\*Plus and is not enabled for other database systems.

Default: `oracle`

## 20.8. Default settings for Export/Import

For some switches of the WbExport and WbImport command, you can override the default values used by SQL Workbench/J in case you do not provide the parameter. The default values mentioned in this chapter apply, if no property is defined in the `workbench.settings` file. The current default for these properties is displayed in the help message when you run the corresponding command without any parameters.

### Controlling header lines in text exports

Property: `workbench.export.text.default.header`

Possible values: `true, false`

This property controls whether default value for the `-header` parameter of the [WbExport](#) command.

Default: `false`

### Controlling XML export format

Property: `workbench.export.xml.default.verbose`

Possible values: `true`, `false`

This property controls whether XML exports are done using verbose XML or short tags and only basic formatting. This property sets the default value of the `-verbosexml` parameter for the [WbExport](#) command.

Default: `true`

### Setting default for WbImport's `-continueOnError` parameter

Property: `workbench.import.default.continue`

Possible values: `true`, `false`

This property controls the default value for the parameter `-continueOnError` of the [WbImport](#) command.

Default: `false`

### Setting a default for WbImport's `-header` parameter

Property: `workbench.import.default.header`

Possible values: `true`, `false`

This property controls the default value for the parameter `-header` of the [WbImport](#) command.

Default: `true`

### Setting a default for WbImport's `-multiLine` parameter

Property: `workbench.import.default.multilinerecord`

Possible values: `true`, `false`

This property controls the default value for the parameter `-multiLine` of the [WbImport](#) command.

Default: `false`

### Setting a default for WbImport's `-trimValues` parameter

Property: `workbench.import.default.trimvalues`

Possible values: `true`, `false`

This property controls the default value for the parameter `-trimValues` of the [WbImport](#) command.

Default: `false`

## 20.9. Controlling the log file

When SQL Workbench/J initializes the logging environment, it also adds two system property that can be used to define the logfile relative to the configuration or the installation directory:

- `workbench.config.dir` contains the full path to the configuration directory
- `workbench.install.dir` contains the full path to the directory where `sqlworkbench.jar` is located

These properties can be used to put the logfile into the directory relative to the config or installation directory without the need to hardcode the directory name.

### 20.9.1. Configure internal logging

#### Log file location

Property: `workbench.log.file`

Defines the location of the logfile. By default, the file will be named `workbench.log` and will be written into the [configuration directory](#).

#### Log level

Property: `workbench.log.level`

Set the log level for the log file. Valid values are

- DEBUG
- INFO
- WARN
- ERROR

Default: INFO

#### Log format

Property: `workbench.log.format`

Define the elements that are included in log messages. The following placeholders are supported:

- {type}
- {timestamp}
- {message}
- {error}
- {source}
- {stacktrace}

This property does not define the layout of the message, only the elements that are logged.

If the log level is set to DEBUG, the stacktrace will always be displayed even if it is not included in the format string.

If you want more control over the log file and the format of the message, please switch the logging to use [Log4J](#).

Default: {type} {timestamp} {message} {error}

#### Logging to the console

Property: `workbench.log.console`

Defines whether SQL Workbench/J logs messages additionally to the standard error output

Default: false

#### Logging SQL used for retrieving metadata

Property: `workbench.dbmetadata.logsql`

If this is set to true the SQL queries used to retrieve DBMS specific meta data (such as view/procedure/trigger source, defined triggers/views) will be logged with level INFO.

This can be used to debug customized SQL statements for DBMS's which are not (yet) preconfigured.

Default: `false`

## 20.10. Configure Log4J logging

### 20.10.1. Turn on Log4J logging

Property: `workbench.log.log4j`

If you need more control over the logfile (e.g. for batch processing) you can delegate logging to Log4j. You can turn on Log4j logging in two different ways:

- The value of the property is `true`
- The value of the property points to an existing file

If you just pass `true` as the value for this property, the Log4j configuration file must be accessible to Log4j through the usual ways (please refer to the Log4j manual for details). If you specify a configuration file, this will be "passed" to Log4j by setting the system property `log4j.configuration` to contain the correct "file URL" needed by Log4j.

When passing a configuration file through this property, you can use a system property as part of the filename (e.g. `${user.home}/sqlworkbench.log`). If the filename denotes a relative filename (e.g. `log4j.xml` without any path information), then it is assumed to be relative to the [configuration directory](#).

When you turn on Log4J logging, you must copy the Log4J library as `log4j.jar` into the directory where `sqlworkbench.jar` is located. Do not include the version number in the filename.

The jar file must be named **log4j.jar**

If the Log4J classes are not found, the built-in logging will be used (see above)

When Log4J logging is enabled, none of the logging properties described in the previous section will be used. You have to configure everything through `log4j.xml`.

When using Help » Show log file with Log4J enabled, and you have configured Log4J to write to multiple files, only the first file will be shown.

When SQL Workbench/J initializes the logging environment, it also adds two system property that can be used to define the logfile relative to the configuration or the installation directory:

- `workbench.config.dir` contains the full path to the [configuration directory](#)
- `workbench.install.dir` contains the full path to the directory where `sqlworkbench.jar` is located

These properties can be used to put the logfile into the directory relative to the config or installation directory without the need to hardcode the directory name in `log4j.xml`

A sample `log4j.xml` can be found in the `scripts` directory of the SQL Workbench/J distribution.

The system properties that are set by SQL Workbench/J to point to the configuration and installation directory (see above) can also be used in the `log4j.xml` file.

## 20.11. Settings related to SQL statement generation

### Controlling schema usage in generated SQL statements

Property: `workbench.sql.ignoreschema.\[dbid\]=schema1,...`

Define a list of schemas that should be ignored for the [DB ID](#). When SQL Workbench/J creates DML statements and the current table is reported to belong to any of the schemas listed in this property, the schema will not be used to qualify the table. To ignore all schemas use a \*, e.g. `workbench.sql.ignoreschema.rdb=*`. In this case, table names will never be prefixed with the schema name reported by the JDBC driver. The values specified in this property are case sensitiv.

Note that for Oracle, tables that are owned by the current user will never be prefixed with the owner.

Default values:

```
.oracle=PUBLIC
.postgresql=public
.rdb=*
```

## Defining CREATE TABLE templates for WbCopy

Property: `workbench.db.[dbid].create.table.[typename]`

This defines a complete CREATE TABLE statement that is used by [WbCopy](#) to create the target table. The `typename` value is the value that has to be used for the `-tableType` parameter of the `WbCopy` command.

The following placeholders are supported in the template

`%fq_table_name%` replaced with the fully qualified table name  
`%table_name%` replaced with the specified table name (without schema or catalog)  
`%columnlist%` replaced with the column definitions (for all columns)  
`%pk_definition%` replaced with the primary key definition.

The placeholder `%pk_definition%` can be used if the DBMS does not support defining a primary key using an ALTER TABLE on the created table. If this placeholder is present in the template and the table has a primary key, the placeholder will be replaced with an appropriate PRIMARY KEY (`col1, ...`) expression. Note that the template must **not** contain the needed comma for the PRIMARY KEY. The comma will be added by SQL Workbench/J if a primary key is defined. If the table has no primary key, the placeholder will automatically be removed.

Default values:

```
.postgresql.create.table.temp=CREATE LOCAL TEMPORARY TABLE %fq_table_name%
( %columnlist% ) ON COMMIT DROP
.oracle.create.table.globaltemp=CREATE GLOBAL TEMPORARY TABLE %fq_table_name%
( %columnlist% ) ON COMMIT DELETE ROWS
.h2.create.table.temp=CREATE LOCAL TEMPORARY TABLE %fq_table_name% ( %columnlist
% )
.informix_dynamic_server.create.table.temp_nolog=CREATE TEMP TABLE
%fq_table_name% ( %columnlist% %pk_definition% ) WITH NO LOG
```

## System generated names for constraints

Property: `workbench.db.[dbid].constraints.systemname`

Defines a regular expression to identify system generated constraint names. If a constraint name is identified as being system generated, it is treated as if no name was defined, when e.g. creating the SQL for a table. Whether or not SQL Workbench/J then generates a name for the constraint can be controlled in the options for the [DbExplorer](#).

Default values:

```
oracle: ^SYS_.*
```

mysql: PRIMARY

## Controlling the chunk size for WbDataDiff

Property: `workbench.sql.sync.chunksize`

Controls the number of rows that are retrieved from the target table when running [WbDataDiff](#) or [WbCopy](#) with the `-syncDelete=true` parameter.

Default value: 25

## 20.12. Customize table source retrieval

SQL Workbench/J re-generates the source of a table based on the information about the table's metadata returned by the driver. In some cases the driver might not return the correct information, or not all the information that is necessary to build the correct syntax for the DBMS. In those cases, a SQL query can be configured that can use the built-in functionality of the DBMS to return a table's definition.

This DBMS specific retrieval of the table source is defined by two properties in `workbench.settings`.

### Defining the SQL statement

Property: `workbench.db.\[dbid\].retrieve.create.table.query`

This property defines the SQL query that should be executed. It must be a statement that returns a result set. The statement may contain three placeholders: `%catalog%`, `%schema%` and `%table_name%` that are replaced with the values of the actual table before running the statement.

### Defining the result column

Property: `workbench.db.\[dbid\].retrieve.create.table.sourcecol`

The source of the table might not be returned in the first column of the result set. If this is the case this property can be used to define the column index in which the table's source is available. The first column has the index 1.

The following example configures a SQL statement to retrieve the table's source using MySQL's "SHOW CREATE TABLE":

```
workbench.db.mysql.retrieve.create.table.query=show create table %catalog%.%table_name%
workbench.db.mysql.retrieve.create.table.sourcecol=2
```

If an error occurs during retrieval, SQL Workbench/J will revert to the built-in table source generation.

## 20.13. Filter settings

### Controlling the number of items in the pick list

Property: `workbench.gui.filter.mru.maxsize`

When saving a filter to an external file, the pick list next to the filter icon will offer a drop down that contains the most recently used filter definitions. This setting will control the maximum size of that dropdown.

Default value: 15
